patients under treatment during the year ending Oct. 1st 1903, was 10,484; of these, 4921 were discharged cured, 3480 were relieved, 603 were discharged on other grounds, and 758 died, leaving 722 patients in the infirmary at the end of the year. Of those cases 3831 were medical and 5931 were surgical. The total number treated showed an increase of 523 over the total treated in the previous year. The average daily number of children treated was 63, against 62 in the previous year; the average daily number of patients was 743, against 725; the largest number of these on any one date was 773, against 770. The average time each patient was under treatment was 25·8 days, against 26·6. Of the cases admitted Edinburgh furnished 5053, Leith 539, and the country 4209. In the out-patient department 31,801 patients had been treated. The ordinary income amounted to £32,685 11s. 1d., as against £32,621 6s. 4d. in the preceding year. The voluntary contributions showed a net decrease over all of £139 14s. 8d. The revenue from hospital tickets and income-tax recovered had amounted respectively to £244 12s. and £62 11s 8d. more than in 1902. The ordinary expenditure amounted to £47,600 18s. 1d., or £407 7s above that of the previous year, an increase which was more than accounted for by the increase in the average number of occupied beds. The expenditure for the year, including out patient department, per occupied bed was £64 1s. 3¾d., or a decrease of £1 0s 7d on the previous year. There had been a reduction of 7s. 0¼d. in maintenance and of 10s. 9¼d. in medical expenditure for each occupied bed. The legacies and donations of £100 and upwards amounted to £47,002 16s. 3d. The average number of nurses and probationers during the year was 210; there were 642 applications for admission during the year, as against 627 in the previous year. The managers had introduced several changes in the nursing department during the past year, the principal being as follows: 1. The abolition of the practice of taking nurses for a two years' course of training. All nurses must now go through a three years' curriculum. 2. The dividing up of the one year's night duty into two periods of six months with an interval of at least six months' day duty. 3. A system of preliminary examination for candidates. Various new works had been completed during the past year. The bathing department was opened in February and had supplied a want long felt. In three surgical pavilions plumbing and drainage reconstruction had been commenced. Fire escape staircases had been completed in all the medical blocks and the escapes on the surgical side had been so perfected as to reduce danger from fires to a minimum. Arrangements had been made with the fire brigade to have a fireman constantly in attendance in the infirmary. The ophthalmological and ear and throat pavilions had been completed and furnished and were now occupied. A very much improved skin department and a medical electrical department were being arranged for. At the convalescent house, Corstorphine, 1290 patients had been admitted during the year; of these, 985 remained the full period of three weeks, during which they gained on an average 4·46 pounds in weight. A new rule had been introduced with regard to the medical staff to the effect that ordinary physicians and surgeons should retire at the age of 65 years. The rule, however, was not to apply to those members of the staff who were at present serving their second or third term of five years in charge of wards or to the professors. Further, the charge of the women students' wards was henceforth to be regarded as a full charge and was to count towards the full term of office. The report was unanimously adopted. A motion was then made by Mr. J. F. M'Lennan, advocate, that the age limit should be applied to the professors as well as to the extramural physicians and surgeons. Sir Charles Pearson moved as an amendment that the question be remitted to the managers. On a vote being taken the motion was carried by 46 votes as against 23 for the amendment.

Theories of the Determination of Sex.

At a meeting of the Aberdeen University Medical Society held on Jan. 8th Mr. J. Arthur Thomson, the professor of zoology, gave an address on the Determination of Sex. He said that there were three theories which of the many that had been put forward had, in his opinion, stood the most severe modern tests. The first of these was that *ab initio* there were male and female ova and male and female spermatozoa, the coalition of corresponding elements resulting in a male or a female. This dimorphism was noticeable in rotifers, in some crustaceans, and, according to Dr. Beard of Edinburgh, in the common skate. The second theory was that the production of male or female offspring depended on the relative freshness or staleness of the male and female elements at the time of fertilisation, the offspring following the sex of the relatively more vigorous progenitor. This theory was supported by the observations of many breeders of domestic animals. The third theory was that environment, e g., nutrition, gave to an originally indifferent embryo the
bias to the side of masculinity [illegible]
rally producing males and go[illegible]
This theory was not opposed [illegible]
first theory it was supposed that the sex was wholly dependent on dimorphism or in the second theory on the relative freshness or staleness of the two elements. It was rather complementary to the two previous theories. The same hydra could be made at one time by good feeding to produce only ovaries and at another time by starvation to
produce only testes. [illegible]
could be made male or [illegible]
respectively with the gr[illegible]
the prothallus of a fern. Similar experiments had been made on caterpillars, but must now be regarded as irrelevant, for there was definite evidence that the sex was predetermined, quite apart from external conditions. In ordinary circumstances the frog's spawn produced 57 per cent. of females and 43 per cent. of males. The percentage of females could be raised to 68, 81, and 92 by feeding the animals with meat, fish, and frog respectively. Unfortunately these results were vitiated, as was also the case in caterpillar experiments, by the mortality not being recorded. The view that there was an essential masculinity about the spermatozoon or an essential femininity about the ovum was untenable. Each element contained characteristics of the other element in addition to its own. The drone bee came from an unfertilised egg. Parthenogenesis was also seen in the plant lice, which could produce offspring in a hot-house for four years without the intervention of a male. The first brood of the wild humble bee consisted of females

born in the spring, but in autumn, or when the temperature was lower, males made their appearance. Out of the five eggs of a sparrow-hawk three became males and two females, male and female alternating; one could not, he thought, physiologically conceive an ovary being able to liberate alternately an *ovum which should become a* male and one which should become a female. The rotifer hydatina had two sorts of eggs, large and small. The large eggs produced only females, the small eggs only males, and no amount of change in environment could produce a male from a large egg or a female from a small egg. Among animals higher in the scale of development mice were very suitable to experiment with as they were ready for reproduction when seven weeks old and, if they were not allowed to suckle their young, could produce a litter every three weeks. Professor Thomson thought that there was at least a strong probability that every ovum of an organism with separate sexes had from the first a predisposition towards becoming a male or towards becoming a female, but that this predisposition might be altered by the nutrition of the ovum, by changes in the period before fertilisation, by fertilisation itself, and by environmental influences (of nutrition, temperature, &c.) during embryonic or even larval life, until the period was reached when the sex of the offspring was fixed. The probability was that many factors determined the result and that insistence upon any one was almost certain to be fallacious.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

University Education in Ireland.

THE question of university education for Ireland would seem to be about to enter again into the sphere of practical politics. It will be remembered that the commission appointed by Lord Cadogan reported against the Royal University as a possible solution of the problem, while Trinity College was expressly excluded from its consideration. Since then the board of the University of Dublin has offered to establish a Presbyterian chapel without the precincts of Trinity College and a Roman Catholic chapel as well if required. A very important letter has recently appeared from Lord Dunraven dealing with the whole matter. Lord Dunraven's proposal is not new but it carries weight on account of the favourable way in which it has been received. His suggestion is that the University of Dublin should be enlarged in order to include not only Trinity College but a fully endowed and equipped college in Belfast to meet the requirements of the Presbyterian students who form the majority there and a third similarly endowed college in Dublin to satisfy the feelings of the Roman Catholics who chiefly centre there. He suggests that the latter might be called "King's College" and that it would be open to Protestant students just as Trinity College is open to Roman Catholics now.

The Fate of Dr. J. R. Welland, Lieutenant R.A.M.C.

Dr. J. R. Welland, Lieutenant R.A.M.C., whose death is reported as having occurred in the recent fighting in Somaliland, was educated at Rossall School and Trinity College, Dublin. He was a thoroughly good man at his work and also a fine oar, stroking the Trinity College crew at Henley four years ago. His death, for there seems no doubt that the worst has happened, will be much felt.

Royal Victoria Hospital, Belfast.

At a meeting of the board of management of the Royal Victoria Hospital, Belfast, held on Jan. 7th, it was announced that the Misses Riddel, of Beechmount, Belfast, had contributed £10,000 to the funds of the hospital as a memorial of the late Mr. Samuel Riddel, a member of one of the oldest and most respected Belfast families. £2000 are earmarked for a residence for the medical superintendent. One of the unnamed wards is to be called the "Riddel" ward. 100 guineas were also handed in as a first instalment of the proceeds of an amateur concert organised by the employés of one of the mills of the York-street Flax Spinning Company of Belfast.

The Poor Consumptive in the North of Ireland.

Mr. R. Brown, the local secretary of the Society for the Prevention of Consumption and other Forms of Tuberculosis, writes to the Belfast press contrasting the car taken in Ireland to stamp out small-pox, while 10,000 times as many deaths are due to consumption, to prevent the spread of which little is done. Some attention is being drawn to the matter in Belfast, but Lisburn, says Mr. Brown is in a worse condition with regard to consumption, while the rural districts are being more than decimated by the whit plague. He urges the urban and rural councils to mak a rate (as has been done in Cork) so as to bring the benefits of sanatorium treatment within reach of all sufferers The educating effect of a month's residence in such institutions would be of the greatest value. Mr. Brown points ou. how utterly unsuited for the purpose of sanatoriums workhouses would be while there are numbers of country houses with beautiful, well-sheltered grounds lying vacant all over Ireland which would suit admirably. It is not want of opportunity but want of interest which prevents progress in the matter.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Out-patients at the Hospitals and Dispensaries.

THERE is at Paris in the hospitals and dispensaries of the Assistance Publique a very complete system for the giving of gratuitous advice and the poor may there obtain all necessary information for the treatment of illness in their own homes. Advice has always been given hitherto in the course of the day and generally in the forenoon, but the municipal representative for the Quartier du Mail, M. Léopold Bellan, will at the next meeting of the municipal council propose that similar opportunities should be given in the evening as well. His arguments in support of the innovation will be as follows. Under the present arrangements many workmen lose too much time in attending the hospitals and sometimes their employers object to it. They put off seeing a medical man as long as possible and from this cause derangements of health which might perhaps have been insignificant if treated at the beginning become aggravated through neglect, until the patient is at last unable to work and may even have to go into a hospital. This misfortune would be avoided if advice were given in the evening when the working classes have left their employment for the day. Even as a question of municipal interest there would be an advantage in poor persons having an opportunity of seeing the medical officers of the Assistance Publique as soon as they felt themselves unwell, for if the illness were taken in time fewer days in hospital would have to be paid for and less relief would be required for destitute families. M. Bellan knows that the medical officers of the Assistance Publique have a great deal to do and he does not wish to overwork them. He only wishes that the experiment should be tried of having one or two evening attendances a week in each hospital district *(circonscription hospitalière)* which could be done by their medical officers giving two hours in the evening once every three weeks. M. Bellan professes to know that the Assistance Publique takes a favourable view of his proposal.

A Victim of Hypnotism.

A remarkable and complicated case has just come before the judicial authorities at Versailles. A woman is alleged to have committed suicide in consequence of the criminal machinations of a person who hoped to inherit the property of the deceased and accordingly suggested suicide to her. It will have to be ascertained in the first place whether the facts are as stated and in the second place whether the offence, if any, is punishable, for questions relative to hypnotism were not foreseen a century ago when the statute was drawn up. An outline of the case is as follows. A married couple named C., very respectable people of independent means living at Marly-le Roi, had for neighbours a married couple named M. The two families soon became friendly but Monsieur C., finding that his wife's head was turned by spiritualistic procedures with which Monsieur and Madame M. occupied themselves, forbade the latter to come to his house. Until the death of Monsieur C.

two years ago the M. family kept themselves in the background, but the prosecution alleges that Madame M. now resumed her former acquaintance with his widow and easily gained her confidence. Monsieur M., it should be remarked, was very old and infirm and seems not to have known what was going on. The two women practised table turning, invoking various spirits, and among them that of the late Monsieur C., who was constantly made to say that he was impatiently waiting for his wife to rejoin him. The widow's mind soon became affected and her health declined by degrees. The *séances* were held every day and at last the deceased insisted that his wife must come to him not later than the end of the year 1903. According to the prosecution Madame M. in the darkened room imitated the voice of Monsieur C. Moreover, she obtained from Madame C. a will in her own favour disinheriting the natural heirs of the testatrix. The widow told everybody that she could not long survive her husband and that she would disappear before the end of the year. Towards the second fortnight of December she directed her tradespeople not to supply her with anything more and she died suddenly on Dec. 22nd. The death was at that time supposed to be due to natural causes and the funeral took place, but when it was found that the deceased had bequeathed everything to Monsieur and Madame M. suspicion was aroused and a judicial inquiry was opened. [illegible] will be very difficult to determine whether the cause [illegible] death was natural or not It will also be matter r consideration whether Madame C. at the instigation of r friend hastened her own death for the purpose of joining her husband, and whether the mental excitement of e spiritualistic meetings might have contributed to the tal issue. During a search made by the police at the sidence of the M family numerous pamphlets on occult iences, spirit photographs, and bottles of laudanum and gitalis were discovered. A similar search was made at the sidence of Madame C., but all her correspondence, papers, id accounts were found to have passed into the possession Madame M. who is now in prison at Versailles. The ecropsy showed that death was due to rupture of the uscular wall of the heart, a lesion which would dispose of ie hypotheses of poisoning or suicide, but portions of the iscera have nevertheless been taken for analysis.

Sleeping Sickness.

The readers of THE LANCET will not have forgotten the ccount[1] which I have already given of this strange disease [illegible] of the tsetse fly. Three [illegible] were recently shown before [illegible] vere then transferred to the hospital of the Association des Dames Françaises at Auteuil. he youngest of the three, Bobenghi by name, died on ec. 7th, 1903, at the age of 14 years. The final stage of his llness was one of those cataleptic attacks which frequently ccur in young patients suffering from sleeping sickness. On Jan. 6th, 1904, Makaya, aged 30 years, succumbed n his turn. His death was unexpected, for he seemed to be [illegible] o be less ill than the remaining [illegible] ived him but who, nevertheless, is [illegible] particular complications but his attacks of sleep were more profound than usual. Saloman lept nearly all day and could with difficulty be awakened to ake nourishment. Sleeping sickness continues to make errible ravages in French Congo and in three years' time out of 100,000 negroes 38 000 have fallen victims to it. Despite the efforts of Dr. Wurtz and of the other medical men who are studying the disease but little advance has yet been made as to its treatment. Makaya lived for six months after being bitten.

Jan. 12th

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Sodium Sulphocyanide in the Treatment of Syphilitic Headache.

Dr. Pauli recommends sodium sulphocyanide (NaCNS) in he treatment of syphilitic cephalalgia. In the pre eruptive tage of syphilis, when painful headache occurs, small doses of this substance (from four to eight grains per day) have a salutary effect. Also in the later stages of syphilis if there is tormenting dull headache not confined to any particular region and with characteristic exacerbation during the night 30 grains of sodium sulphocyanide per day are often very useful.

A Peculiar Skin Disease in Butchers.

Dr. Matzenauer has observed six cases of a peculiar dermatosis in persons employed in butchers' shops. The patients had thickening of the skin on the hands and fingers very similar to keratoma The thickening might amount to as much as one-fifth of an inch and the surface of the skin was so thickly covered with pits and depressions that it almost resembled a sponge; the affection was localised on the palm. There was never any inflammation surrounding the callosities. The disease showed the same appearance as keratoma palmare (et plantare) hereditarium, but it differed from that condition inasmuch as it did not develop in childhood but only in adult life and disappeared when the patients changed their occupation. It was also different from chronic eczema with callosities. In keratosis arsenicalis the thick hard skin has a coarse uneven surface, not the peculiar sponge-like honeycombed surface of the dermatosis now described. All the patients worked in butchers' shops, where they were employed in removing hair from pigs by immersing them in hot water and rubbing them with colophony. The disease was due to the combined effect of hot water and colophony. Hot water itself caused only eczema lotricum, as met with in laundresses and bath attendants, but colophonia made the epidermis loosen and swell and this was the cause why butchers used it for the removal of hair from the carcasses of pigs. Histological examination of the skin in this disease showed only pure hyperkeratosis.

Reflex Effects on the Pulse.

The researches of Dr. Heitler have already shown that mechanical irritation (1) of the region of the liver or heart, and (2) of the sternum, skin, muscles, bones, and mucous membranes increases the volume of the pulse. Further investigations have proved that mechanical irritation of the above-mentioned regions may also cause a diminution of the pulse. Percussion on the region of the liver, heart, or sternum makes the pulse rise, but pressure on the same regions reduces the pulse during the continuance of the pressure. In many individuals Dr. Heitler observed that diminution of the pulse was produced by shutting the eyes and that the pulse increased again on opening the eyes. This effect was evidently due to the influence of light.

Jan. 11th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Prevalence of Scarlet Fever.

SCARLET fever has become epidemic to an alarming extent at Mount Morgan, Queensland. The hospital accommodation is taxed to its utmost limits and arrangements have been made for extra temporary accommodation for the patients.

Preservatives in Food.

In March last the Board of Health of New South Wales made certain regulations with regard to the use of preservatives in food to which reference has been previously made in these columns. In consequence of representations from various industries affected by these regulations a select committee of the Legislative Assembly was appointed to inquire into the question. The conclusions of the committee were as follows:—

[illegible] mental committee and [illegible] the amount fixed as permissible by the regulations of the Boards of Public Health both in New South Wales and Queensland.

[illegible] regards milk, if there is sufficient care in handling and [illegible]

maintenance, expansion, and [illegible]

---

[1] THE LANCET, August 29th (p. 636), Oct. 31st (p. 1263), and Nov. 14th). 1403), 1903.

this nutritious article of food within the reach of every householder at a reasonable price, the use of 18 grains of boracic acid to the pound is necessary.

6. That the use of 35 grains of boracic acid to the pound of butter and 35 grains of boracic acid to the pound of concentrated milk and 18 grains of boracic acid to the pound of table cream will cause no injury to health and should be permitted.

7. That having in view the right of people to know what any food stuff consists of, vendors of those articles containing preservatives should include on the label on the package, tin, or containing vessel, and in conformity with the rest of the label a statement setting forth the nature and quantity of the preservative contained therein; and in cases where a label is not ordinarily fixed then a special label to that effect should be affixed.

And your committee recommend that the regulations made under the Public Health Act should be amended and brought into conformity with the above conclusions.

The Birth-rate Commission.

The President of the Birth-rate Commission in New South Wales has applied for an extension of time in which to send in a report. It is believed that evidence taken will show that it is the women of the community who are opposed to families, partly on the ground of the physical pain of childbearing and partly owing to the restriction of duties and pleasures resulting from maternity. The evidence of druggists is said to show that there is a large sale of "preventives," chiefly to women of the upper and middle classes. The distaste for child-bearing is shown to bear a corresponding ratio to "intellectual" status. This goes side by side with postponement of marriage in the same classes, and curiously enough, with certain nationalities. For example, the births to women born in New South Wales average considerably lower than to those born in any part of the United Kingdom and most European countries.

Infant Mortality.

Not only is there a declining birth-rate but also an excessive infantile mortality in New South Wales. With a view of diminishing this in Sydney Dr. W. G. Armstrong, the health officer, has recommended that a formula for the proper care and feeding of infants should be prepared, printed, and sent by post to all households in thickly populated and poor districts in which a birth had been registered during the last six months.

Care of Neglected Children.

At a conference of the Christian Union Senator Dr. Mackellar stated that during the last 20 years between 11,000 and 12,000 children had been dealt with by the State Children's Relief Board. He found that children whose fathers had deserted them and whose mothers were unable to support them numbered 2885; in 690 cases the fathers were in gaols and the mothers were destitute; in 282 the fathers were drunkards and the mothers were unable to support them; in 3284 the fathers were dead and the mothers were unable to support them; in 318 the mothers were prostitutes; in 137 the children were foundlings; in 31 the fathers had deserted them and the mothers were living in adultery; and in 97 the fathers were dead and the mothers were living in adultery. He had very good evidence that these children, removed from their vicious surroundings and placed in properly conducted homes, were no worse than the ordinary members of the community.

Lunacy Bill in Victoria.

The Bill to amend the Lunacy Act has been further considered in the Victorian Parliament. The proposal to create a Board of Lunacy was abandoned The salary of the inspector-general, whose responsibilities are very great without a board, was increased to £1500 a year. A provision was inserted that the inspector general must be a medical man.

Proposal to remove the Metropolitan Lunatic Asylums.

A deputation waited on the Premier of Victoria recently to urge that the present sites of the lunatic asylums at Kew and Yarra Bend should be sold and that new buildings should be erected on a less valuable site farther from the city. It was pointed out that the present buildings were so faulty in construction as to be quite unsuitable for the proper treatment of the insane. There were about 800 acres in the asylum reserves valued at £200 an acre. Plenty of land within ten miles of Melbourne suitable for the purpose could be obtained for £10 an acre. The Premier replied that he would take the proposals into consideration and would consult his colleagues but he could promise nothing.

The Treatment of Consumption.

The treatment of consumption by special hospitals and sanatoriums is far from satisfactory in Australia. In New South Wales the movement to commemorate the late Queen Victoria took the form of a fund to establish homes for consumptives. The committee took over the existing home at Thirlmere, which contains 42 beds, and it is always full. The last report shows that 136 patients were received for the year, of whom 96 recovered sufficiently to be able to resume their ordinary duties and in three the disease was completely arrested. During last year the executive committee decided to build another home for the treatment of those afflicted in the very early stage of the disease. Land was purchased and wards to accommodate 20 patients were built, together with administrative quarters for the matron, the nurses, and the resident medical officer. This entailed an outlay of about £5000 and the home or sanatorium, which is situated at King's Tableland, Wentworth Falls, was opened in February last. The committee feels that it is incumbent upon it to supply still further accommodation and this will mean the using up of most of the funds, and will further reduce its income. Neither the public nor the Government, however, seems inclined to provide the necessary funds. In Victoria there are two sanatoriums, one at Echuca, and the other at Macedon, and two country hospitals take a limited number of cases. The provision is utterly inadequate. The committee of the Austin Hospital takes advanced cases and is still squabbling with the Government and the residents of Heidelburg about providing more accommodation with the money given by Mr. Kronheimer for the special purpose.

Hospital Affairs.

At the Royal Prince Alfred Hospital, Sydney, Dr. C. B. Blackbourne has resigned the position of medical superintendent and Dr. A. H. Macintosh has been elected in his place. Dr. Blackbourne and Dr. E. Fairfax have been appointed assistant physicians; Dr. H. Taylor Young has been appointed assistant gynæcologist, and Dr. H. Russell Nolan assistant surgeon for diseases of the ear, the throat, and the nose. The matron, Miss M'Gahey, has resigned and the board will invite applications for her post in Great Britain, Canada, and America

The British Medical Association and the Australian Natives Association in New South Wales.

A well-attended public meeting was held at the Balmain town-hall recently to discuss the relations between the Australian Natives Association and the medical profession. The chairman explained the position of the Balmain branch of the Australian Natives Association. It had been formed in June, 1901, had become affiliated with the Balmain United Friendly Societies' Dispensary, and for 12 months matters had gone along smoothly. Then the dispensary board had been urged by the British Medical Association to sever its connexion with the Australian Natives Association, and in May, 1902, a conference between the dispensary board and the medical officers had taken place, the latter taking up the position that the Australian Natives Association was not a genuine benefit society established for philanthropic purposes but for political purposes, and that it was a society prejudicial to the interests of the medical profession Mr. Martin, president of the Australian Natives Association, said that the British Medical Association had singled out the Australian Natives Association for public attack—and he said public advisedly—because it was a new society and therefore it was thought one that would be easily crushed and made an example of. If it beat the Australian Natives Association then it would go for the other friendly societies. The British Medical Association had no sympathy with friendly societies and had frankly admitted that it would like to see them "wiped out."

Obituary.

The profession in Melbourne has suffered a great loss by the sudden death of Dr. William Butler Walsh in his forty-ninth year, he having been born at Pau, France, in 1854. Dr. Walsh was the son of the late Rev. E Walsh, a clergyman of the Church of England. He was educated at the Tipperary grammar school and at Trinity College, Dublin, where he graduated as B.A. and M.D. He was also a Fellow of the Royal College of Surgeons in Ireland. For two years he acted as medical officer to the P. and O. Company. He arrived in Melbourne in 1881 and soon established a very extensive practice in Kew. A few months ago he established himself in Collins-street, Melbourne, as a consulting physician. Dr. Walsh was for some years examiner in anatomy in the University of Melbourne. He was recently appointed assistant physician to St. Vincent's Hospital and was a vice president of the Medical Society of Victoria. Dr. Walsh enjoyed in a peculiar manner the esteem of the profession, not only on account of his capability but also because of his great personal charm, his gentle, courteous, considerate manner, his strict maintenance of the best traditions of the profession, and his high moral character, qualities which also gained him the personal friendship and love of all his numerous patients.—Dr. R T. Wylde, who died recently at Semaphore, South Australia, was one of the oldest medical men in that colony. He took his M R C.S diploma 60 years ago. He was the author of a useful book on floriculture and, in his day, was a most popular and capable physician enjoying a large practice.

Dec. 8th, 1903.

Obituary.

ROBERT JAMES BLAIR-CUNYNGHAME, M.D., F.R.C.S., M R.C.P. EDIN., J.P., F.R S. EDIN.

Dr. R J. Blair Cunynghame, who died on Dec. 23rd last at his residence in Edinburgh, was for many years an assistant to the late Professor Saunders who held the chair of pathology in the University of Edinburgh and frequently lectured for him. Though a man of independent means he studiously followed his profession and at various times held several important appointments. He studied medicine in London, Berlin, Prague, and Vienna, and graduated as Doctor of Medicine in the University of Edinburgh in 1862. In the same year he obtained the gold medal of this University for forensic medicine. Four years later he obtained the Fellowship of the Royal College of Surgeons of Edinburgh, of which College he was made President in 1892, and became a Member of the Royal College of Physicians of Edinburgh in 1877. He was a Fellow of the Royal Society of Edinburgh and at one time President of the Royal Medical Society of [illegible] a member of the Edinburgh [illegible] and was an examiner at the Ro[illegible] Edinburgh. He held the post c[illegible] in the Registrar General's department in Scotland, was a late physician of the Royal Hospital for Sick Children, Edinburgh, and was at one time resident physician to the Royal Infirmary, Edinburgh.

HENRY BOYD CARDEW, M.R.C.S. ENG., L.R.C.P. LOND.

Mr. Henry Boyd Cardew, who has just died at his residence, Oriel Lodge, Cheltenham, after a very short illness, was the elder son of Major-General Henry Cardew, a retired officer of the Royal Artillery. Upon leaving Cheltenham College, where his early education was received, he entered at St. Bartholomew's Hospital and eventually took the diplomas of the Royal College of Surgeons of England and the Royal College of Physicians of London in 1890. Returning to Cheltenham he became house surgeon at the General Hospital, retiring from the position of senior house surgeon in 1894 to undertake private practice. But he continued for several years later to hold the position of honorary medical officer to the branch dispensary of the hospital and to the Victoria Home. The deceased was a distinguished figure in local sport and athletics, in the promotion of which he was an energetic worker, and he often figured as a judge at various gatherings, more particularly so at aquatic sports. He was married in 1895 to Miss Agnes Moore, third daughter of Mr. Thomas Moore, F.R.C S., of Blackheath, and leaves a widow and four young daughters to mourn his death. The deceased, who was only 37 years of age, was one of the most popular medical men in Cheltenham and one of the best known and most highly esteemed members of local society.

JOHN ANDERSON, M.R.C.S. ENG.

MANY from the Buchan district of Aberdeenshire will hear with deep regret the news of the death of Mr. John Anderson, which took place on Dec. 9th, 1903, at his residence, The Crescent, Longside, Aberdeenshire, in the ninetieth year of his age. Although it is about a quarter of a century since Mr. Anderson gave up the extensive practice which he carried on in town and country and retired into private life, he is still well remembered by the older natives of the town and district. He was the last survivor of his compeers in Peterhead, Mr. Patrick Jamieson, F.R.C S. Edin., who for long was contemporary with him, having died a few years ago. Mr. Anderson was educated at the University of Aberdeen and became M.R C S. Eng. in 1836. Of somewhat bluff exterior he was a man of kindly disposition and was recognised as a devoted and skilful medical adviser. His wife died about ten years ago and he is survived by an only daughter.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At the primary examination held recently the following candidates passed in the subjects indicated :—

PART I.

Biology.—E. G Brisco-Owen and A. Samuel, Cardiff; and M. V. Webb Royal Free Hospital.
Chemistry.—C J. Wolfe Edinburgh.
Materia Medica and Pharmacy.—J. M. Lynch, Cork, and M. Rathbone, Royal Free Hospital.

PART II.

At[illegible]
Hospita[illegible] J. M. Lynch,
Cork; a[illegible]
Physiolog[illegible]spital; H. J.
Dusko[illegible]ersity College
Hospita[illegible] Lynch, Cork;
and H[illegible]

THE ROYAL FREE HOSPITAL.—Princess Christian [illegible] accompanied by Princess Victoria of [illegible] Royal Free Hospital, Gray's-[illegible]on last, and distributed the [illegible] which she had provided for the patients and nurses.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The annual charter dinner will be held at the College on Saturday, Feb. 13th. His Excellency the Lord Lieutenant has graciously accepted the invitation of the President and council to be present at the dinner. As the accommodation [illegible]present will of necess[illegible] at the dinner [illegible] guest whom they m[illegible] Royal College of Surgeons, Dublin.

DONATIONS AND BEQUESTS.—Miss Louisa and Miss Mary Lawrence have given a donation of £500 to the appeal fund in connexion with St Bartholomew's Hospital in memory of their father. An additional £500 is promised in 1905.—By the will of the late Mr. John Penn, M.P. for Lewisham, a sum of £2000, free of duty, is bequeathed to the Miller Hospital and Royal Kent Dispensary, Greenwich.—Mr. Philip Hedgcock has by his will left £1000 to the Sussex County Hospital, £300 to the Brighton Hove, and Preston Dispensary, and £300 to the Sussex Eye Hospital.

VACCINATION EXPENDITURE.—At a meeting of the Helston (Cornwall) board of guardians held on Jan 2nd it was reported that for the four years 1896-99 previously to the passing of the recent Vaccination Act, 1380 primary vaccinations were performed in the Helston union at a total cost of £314 There was no case of revaccination During the four years subsequent to the enforcement of the Act—namely 1900-03—there were 2317 primary vaccinations and 561 revaccinations performed, the expenditure being £529. Several of the guardians expressed great surprise at the increase in the expenditure and a committee was appointed to petition the Local Government Board on the subject.—At the meeting of the Warmley (Gloucestershire) board of guardians, held on Jan. 5th, it was stated that in the Kingswood, Oldland, and Siston district for the four years preceding the passing of the Vaccination Act 837 vaccinations were performed at a cost of £37, whereas during the four years following the enforcement of the Act there were 845 vaccinations which involved an expenditure of £285. It was also reported that in another district of the union the cost for the four years preceding the Act was £11, while for the four years following the enforcement of the Act it was £130.

Centenarians.—Mrs. Eliza Jenkins, of Otterford, near Taunton, attained the age of 105 years on Jan. 1st; she is stated to be the oldest resident in the county of Somerset.—Mrs. Ann Davies, of Penralltffynnon, Cardiganshire, died very recently, aged 103 years.

Royal Waterloo Hospital for Children and Women, Waterloo road S E, Founded a.d. 1816.—Three original plays specially written by officers of the Channel Fleet were produced at the Queen's-gate Hall, South Kensington, on Jan. 13th, on behalf of this institution which has for the greater part of a century relieved over a million poor children and which is now in urgent need of £50,000 for rebuilding.

The late Mr. D'Arcy Sugden.—Mr. D'Arcy Sudgen died at his residence, Buckfastleigh, Devon, on Dec. 30th, 1903, from pneumonia following typhoid fever which he contracted in the discharge of his professional duties. He was the third son of the late Mr. W. Sugden of Bath and received his medical education at St Bartholomew's Hospital, taking the qualifications of L.R.C P. Lond. and M R C S. Eng. in 1876 and 1877 respectively. Mr. Sugden was for some time in Queensland, Australia, where he held appointments at the Maryborough Hospital and the Bundaberg Hospital. He went to Buckfastleigh about two years ago and at the time of his death was 50 years of age.

Folkestone Medical Society.—The annual meeting of this society was held on Jan 8th at the house of the President, Dr. T Eastes. The following officers were elected:—President: Dr. W. J. Tyson. Vice-Presidents: Dr T. Eastes, Dr. J. Hackney, and Dr. C E. Perry. Committee of Management: Mr. J. W. Thornton Gilbert, Mr. J. R. P. Phillips, Mr. H A. Powell, Dr E. G. Sworder, and Dr. L. Wainwright. Library Committee: Mr. A. Randall Davis, Mr. J. Keay, and Mr. F B. Madden. Honorary secretary and treasurer: Dr. J. E G. Calverley. It was decided to make the following donations from the society's funds: to the Epsom College, £2 2s.; Kent Benevolent Society, £1 1s.; and the Folkestone District Nurse, £1 1s.

Presentation to a Medical Practitioner.—On Jan 7th, at the St John's Jubilee Room, Worcester, there was a large gathering of patients and friends of Dr. J. Ronald Polson, when an elaborately illuminated congratulatory address and a silver tray were presented to Dr. and Mrs. Polson. Dr. Polson, who has practised at St. John's since 1887, has earned the affection of the whole of the inhabitants of St. John's and district and his marriage was made the occasion of presenting to him some tangible form of their esteem. The tray bore the inscription: "Presented to Dr. and Mrs. J. Ronald Polson upon the occasion of their marriage, Feb 29th, 1903, by friends and patients of Dr. Polson. 'I was sick, and ye visited me.'" The subscribers numbered nearly 400, embracing all sorts and conditions of men differing in creed and politics.

Literary Intelligence.—The Orient Press, late the Primrose Press, announces the early appearance of "The Duties of the Heart," translated from the Arabic of Rabbi Bachye, with an introduction by Edwin Collins; "The Sayings of Confucius," "The Odes of Confucius," and "The Sayings of the Brothers of Sincerity." The teachings of this interesting sect, which flourished in Persia and Arabia in the ninth and ten centuries, will be edited with an introduction by Dr. Paul Brönnle. Dr. S. A. Kapadia, secretary of the Northbrook Society, has the general superintendence of the works upon Indian religions and literature which the Orient Press intends to place before the public.—With the February number of *Knowledge* a development of its scope and contents is contemplated by its directors. It has during its 22 years' career been chiefly devoted to astronomy and the natural sciences, but in future it will add physics, electricity, and applied science to these subjects. In order the more suitably to effect this alteration *Knowledge* will be amalgamated with the *Illustrated Scientific News* and will be issued under the title of *Knowledge and the Illustrated Scientific News*.

BOOKS, ETC., RECEIVED.

Association of American Physicians (Secretary, Dr. Henry Hun, 149, Washington-avenue, Albany, N Y.).

Transactions of the Association of American Physicians. Eighteenth Session, held at Washington, D.C., May 12th, 13th, and 14th, 1903. Vol. XVIII. Price not stated.

Baillière, Tindall, and Cox, 8, Henrietta-street, Covent-garden, W C.

A Pocket Dictionary of Hygiene. By C. T. Kingzett, F.I.C., and D. Homfray, B.Sc. Second edition. Price 2*s* 6*d*.

Browne and Nolan, Limited, Nassau-street, Dublin.

Transactions of the Royal Academy of Medicine in Ireland. Vol. XXI. Edited by John B. Story, M B., F.R C.S, General Secretary. With index, Vol. I. to XX, compiled by E J. McWeeney, M D. Price not stated.

City of London Book Depôt, White-street, Moorfields, E C.

Cusack's Biology. By William E. Clarke, A R.C S. (London), Lecturer in Biology at the Day Training College, Moorfields, E C. Part I., Plant Life. Part II., Animal Life. Price 2*s*. 6*d*. net.

Dawbarn and Ward, Limited, 6 Farringdon-avenue, E.C.

Pentland, Young J., Edinburgh and London.

The Edinburgh Medical Journal. Edited by G. A. Gibson, M D., F.R C P Edin., and Alexis Thomson, M.D., F.R.C.S. Edin. New series. Vol. XIV. Price not stated.

Sanitary Publishing Company, Limited, London.

Disinfection and the Preservation of Food. Together with an Account of the Chemical Substances used as Antiseptics and Preservatives. By Samuel Rideal, D Sc. London, Fellow of University College, London; Fellow of the Institute of Chemistry, of the Chemical Society, and of the Sanitary Institute of Great Britain. Price not stated.

Southern Surgical and Gynæcological Association (Secretary, Dr. W. D. Haggard, Nashville, Tenn.).

Transactions of the Southern Surgical and Gynecological Association. Vol. XV Fifteenth Session, held at Cincinnati, Ohio, Nov. 11th, 12th, and 13th, 1902. Edited by W. D. Haggard, M.D. Price not stated.

The Baker and Confectioner, Limited, 61 and 62, Chancery lane, W C.

Studies for the Bakehouse: being Lectures delivered to the Ayrshire Class. By A Kirkland, Irvine. Price not stated.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Andrew, William, M.B., C.M Edin., has been appointed Public Vaccinator for the Lezant District by the Launceston (Cornwall) Board of Guardians.

Barker, F. J., M.B., C.M. Glasg., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

Barwell, Harold, M B. Lond., F.R C S. Eng., has been appointed Assistant Surgeon to the Metropolitan Ear, Nose, and Throat Hospital, Grafton-street, Fitzroy-square.

Bonney, W. F. Victor, M.S., M.D. Lond., F.R.C.S. Eng., M.R.C.P. Lond., has been appointed Lecturer in Practical Midwifery in the Middlesex Hospital Medical School.

Candler, George, B A. Cantab., L.R.C.P. Lond., M R.C S., L.S A., has been appointed Medical Officer and Public Vaccinator for the Black Torrington, Bradford, and Cookbury Districts of the Holsworthy Union (Devon).

Emanuel, J. G, M.D. Lond., M B., Ch.B. Birm., M.R.C.P. Lond, has been appointed Physician to Out-patients at the Birmingham and Midland Free Hospital for Sick Children.

Grey-Edwards, H., M.B., B Ch. Dub., has been appointed Honorary Ophthalmic Surgeon to the Carnarvonshire and Anglesey Infirmary.

Lister W. T., B A., M.B., B.C., F.R.C.S., has been appointed Assistant Surgeon to the Royal London Ophthalmic Hospital, City-road, E C.

Mackenzie, E. G., M.B. Toronto, has been appointed Clinical Assistant to the Chelsea Hospital for Women.

Milward, F. Victor, B A, M.B., B.C. Cantab., F.R.C.S Eng., has been appointed Surgeon to Out-patients to the Birmingham and Midland Free Hospital for Sick Children.

Norman, R. H., M.D. Lond., B S., M.R.C.S., L.R C.P. Lond, has been appointed Assistant Anæsthetist to the Great Northern Central Hospital.

Price, E. O., M D., C.M. Edin., has been appointed Honorary Medical Officer to the Carnarvonshire and Anglesey Infirmary.

Stanm. L. E., M.D., B.A., B.Sc. Lond., has been appointed Medical Officer to the British Home and Hospital for Incurables, Streatham Common S.W.

Thornton, Bertram, M.R.C.S. [illegible] has been appointed Medical Officer of [illegible]

Young H. C. Taylor, C.M., [illegible] Assistant Gynæcological S[illegible] pital, Sydney, New South Wales.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Bradford Workhouse and Hospital.—Resident Assistant Medical Officer, unmarried. Salary £125, with rations, apartments, and washing.

[illegible]—House Surgeon, unmarried. [illegible] and apartments [illegible]

[illegible] iseases of the Chest, Victoria- [illegible] for six months. Salary at rate of £30 per annum, with board, washing, and residence.

[illegible]renth Asylum (Training School and Industrial Colony), near [illegible] and washing.

[illegible]spital for Sick Children, Great Ormond-street, London, W.C.—House Surgeon, unmarried, for six months. Salary £20, with board and residence.

[illegible]ds General Infirmary.—Ophthalmic and Aural House Surgeon. Board, lodging, and washing

[illegible]eds Public Dispensary.—Junior Resident Medical Officer. Salary £100 with board and lodging.

[illegible]cester Infirmary.—Assistant House Surgeon. Salary £80 per annum, with b[illegible]

[illegible]erpool, David [illegible] Surgeon Salar[illegible]

[illegible]erpool Dispen[illegible] per annum, with board and apartments.

[illegible]tional Hospital for the Paralysed and Epileptic, Queen-square Bloomsbury, W.C.—Registrar. Honorarium of 50 guineas.

[illegible]pa Westray, Orkney.—Lady Medical Officer and Public Vaccinator. Salary £[illegible]

[illegible]chdale I[illegible] d. Salary £100 per [illegible]

[illegible]yal Buc[illegible] Surgeon, unmarri[illegible] and apartments

[illegible]yal Ear Hospital, Frith-street, Soho, W.—Honorary Assistant Anæsthetist.

[illegible]estminster General Dispensary.—Honorary Surgeon.

[illegible]rk County Hospital.—House Physician. Salary £100 per annum, with board, residence, and washing.

Births, Marriages, and Deaths.

BIRTHS

[illegible]peman.—On Jan. 9th, at 57, Redcliffe gardens, S.W., the wife of Monckton Copeman, M.D., F.R.S., of a daughter.

[illegible]yward.—On Jan 8th, at Stert-street, Abingdon, the wife of M Cecil Hayward, M.A., M.B., of a daughter.

[illegible]fell.—On Jan 13th, at the Briars, West Hill road S.W., the wife [illegible], the wife [illegible]ester, the [illegible]

MARRIAGES.

[illegible]rdy—Van Breda.—On Jan. 7th, at Wynberg, Cape Town, Major William Edmund Hardy, R.A.M.C., to Florence Minnie, eldest daughter of S. Van Breda, of Hauptville, Wynberg.

[illegible]ayfair—Leighton.—On Jan. 11th, at St. Andrews, N.B., by the Rev. Canon Winter, Ernest Playfair M.B., M.R.C.P., son of the late Sir R. Lambert Playfair, K.C.M.G., to Harriet, daughter of the late Henry Forester Leighton, and grand-daughter of the late John Hall Maxwell, C.B., of Dargavel.

DEATHS.

[illegible]nders.—On Jan. 3rd, at Nice, Charles Edward Saunders, M.D., [illegible]M.R.C.P. Lond., D.P.H. Camb., aged 60 years.

[illegible]obalds.—On Jan. 5th, Arthur John Arundel Theobalds, M.B., [illegible]C.M., of Wargrave, aged 34 years.

[illegible].B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

AN UNDESIRABLE HANDBILL.

The following handbill has been sent to us for our opinion, with a statement that it has been distributed from house to house in the Openshaw district of Manchester.

INDUSTRIAL DISPENSARY

68 BOSWORTH STREET, OPENSHAW.

Open Daily from 9 to 10 A.M., and from 6 to 9 P.M.

Advice and Medicine,	6d.	Visit and Medicine,	1/6.	Midwifery Cases,	15/-.

Resident Physician and Surgeon·

J—— M——, L.R.C.P., M.R.C.S., L.S.A., &c.

(Ex-House Surgeon Preston and Bolton Infirmaries).

THE DISPENSARY WILL BE

OPENED on and after MONDAY, NOV. 16th, 1903.

By Order of the Committee.

We often have to refer to handbills of this kind and there is nothing about J. M.'s specimen that is particularly bad. His fees for advice and visiting are the same that medical officers of many dispensaries have to adopt, while his fee for midwifery is actually a little higher. But such offers of economical medical services should not be distributed broadcast to the patients of other medical men. The only advertisement to which the medical officer of a dispensary is entitled is that which he earns by conducting his professional business in a capable manner.

A CURE FOR STUTTERING.

We have received a pamphlet through the Church Agency, Limited, entitled "A Permanent Cure for Stuttering," written by Herr Theodore Jacobs, who is styled the director of an international institute for the treatment of stuttering The pamphlet goes into the question of the origin of stuttering and purports to show that the infirmity is usually psychical and the author narrates cases in proof of this and also in proof of his ability to remedy the condition. He [illegible] possible to do so as the same thing does not suit everybody." Quite so, but we can imagine many cases the cure of which is not quite so simple as Herr Theodore Jacobs imagines. What, in such circumstances, becomes of the boarder at "Schloss X——"—a somewhat dignified name for a three-storeyed house with a door in the middle and three windows on each side? What becomes of him if conversation with the "Professor" or his assistant leads to no good result? We perceive that payment is made for board, lodging, and instruction in all branches one month in advance, the sum demanded being very moderate We perceive, also, that every boarder who neglects his studies can be dismissed without any part of his payment being returned It seems to us that Herr Theodore Jacobs, when he got hold of a severe case, could always send the patient away as an idle student and need not return the cheque We are not suggesting that this will happen or that it has happened. We are pointing out that, for all the prospectus shows to the contrary, it might happen.

STREET MAPS FOR PUBLIC REFERENCE.

To the Editors of THE LANCET.

Sirs,—How many Londoners are there who can boast that they even superficially know the topography of the city wherein they live? I would suggest that if we require maps to guide us rightly around the Zoological Gardens, parks, and other public places, we require them far more to guide us in the intricate labyrinth of London streets. I know that there are lots of excellent pocket maps to be obtained but it seems to me that large maps might well be provided out of the rates Why cannot we have official maps of London neatly framed in weather proof cases displayed in convenient and important parts of the metropolis to guide the weary wayfarer who cannot carry a Kelly's Directory in his head? I am, Sirs, yours faithfully,

DÆDALUS.

London, Jan 9th, 1904.

BIRD "PRESERVING."

"A fine specimen of the rose coloured pastor was shot the other day by Mr. Buggins of —— It has been entrusted to the care of Mr. Juggins, taxidermist, for preservation." So, or in some similar way, runs an all too common paragraph in the daily press. Mr. E. Kay Robinson thinks as we do that such exploits are pitiable and he writes to the *Times* of Jan. 11th to put on record a rare piece of self-denial on the part of a gamekeeper at Holkham who might have shot a waxwing on two occasions but preferred to "preserve" it in another way. Mr. E. Symonds, the gamekeeper in question, deserves the public compliment that has been paid him. How many people seem to regard collecting dead specimens as a proof of knowledge of live animals. And how often the keen collector is really quite ignorant of natural history, though by the help of manuals he can class his flower, his beetle, his moth, or his bird.

RED OR BLACK INK FOR PLACARDS.

To the Editors of THE LANCET.

SIRS,—Your correspondent remarks very sensibly and very usefully on the tendency of the red ink with which many placards are printed to fade and on the indistinct appearance of initial letters in red as compared with the remaining letters of a word in black.

No colour is so cheap, so easy to print, or so permanent as black; some reds, however, such as those made with oxide of iron, sulphide of mercury or alizarin (from madder), are very fairly permament, but many of the most beautiful reds being made from anilin are very fugitive.

The best initials, in my opinion, are those in which the form of the letter is of the same colour—say black—as the rest of the word, its ornamental surroundings being of a different colour—say red.

A plain initial in black, the rest of the word being in red, though not common, would probably prove a good arrangement for catching the reader's eye.—I am, Sirs, yours faithfully,

THEODORE MAXWELL, M.D. Cantab., B.Sc. Lond.,
Honorary Secretary, Amateur Printers' Association.
Woolwich Common, Jan. 11th, 1904.

THE PRESCRIBING OF NAPHTHALIN.

To the Editors of THE LANCET.

SIRS,—In a well-known text-book on "Diseases of Children" it is stated: "Naphthalin is an effective anthelmintic for threadworms." I am writing to ask how it should be dispensed to overcome the disagreeable taste and what dose is suitable for a child five years old and what for an adult. I am, Sirs, yours faithfully,

Jan. 12th, 1904. M.D. (VICT.).

*** The average adult dose of naphthalin is two to 15 grains, which may be given in cachets or in pills. Numerous references to its employment for threadworms are given in Martindale's Extra Pharmacopœia.—ED. L.

FRENCH QUACK MEDICINES.

A CORRESPONDENT has sent us a circular which he found slipped between the pages of a French magazine and which sets forth in the usual style the advantages of a preparation for anæmia, called Confiture de St. Vincent de Paul. Our correspondent says that an advertisement of the same "cure" also frequently appears in the pages of English Roman Catholic newspapers. There is nothing more disgusting than the way in which vendors of quack medicines call in the aid of religion to puff their wares and some religious houses are not above selling quack medicines. St. Vincent de Paul was a very able organiser and a shrewd man of the world, as well as a saint, and were he alive now he would certainly view with disfavour the attempt to extract money from the pockets of the sick by the attaching of his name to what is probably a simple purgative.

THE JUNGFRAU RAILWAY.

MR. George E. Walsh, writing on Mountain-climbing Railways in a recent number of the New York *Electrical Review*, says that the station at Eigerwand which has just been opened is the third station on the electric railway up the Jungfrau and is at an altitude of 9405 feet The electric railway commences at Scheidegg where the steam railway from Lauterbrunnen and Grindelwald ends. This point is 6160 feet above sea level. The first station is at Eiger and the second station is at Rothstock, which is at an altitude of 8270 feet and is two miles from the starting point. The fourth station is at Eismeer and has an altitude of 10,355 feet. This station is completed and the line as far as here is nearly ready for operation. From this point the line will run in time to Jungfraujoch, 11,090 feet, and eventually to Jungfrau, a total height of 13 488 feet, the actual summit of the mountain having a height of 13 670 feet. The gradient of the road in its first four sections is from 15 to 25 per cent. One of the many obstacles which the engineers had to encounter was the employment of men able to work in such a rarefied atmosphere. At 10,000 feet altitude comparatively few men can do hard work for many hours a day; but the selected men from the north of Italy were able to respond to the demands made upon them better than was expected. Mountain sickness frequently thins their ranks and fresh hands have to be obtained from below, but these new men have to be accustomed to the high altitudes by degrees. At 13,000 feet they may have to work in shifts of two hours at a time and then to return to lower levels for rest and recuperation. The company constructing the line pays great attention in every way to the health and comfort of the men. The gauge of the railway is 39 inches. The locomotives are worked by two three-phase motors of various types. The following is reproduced *verbatim*: "The trains are made up of a small locomotive and two trailers coupled on behind. Complete this train weighs about 28 tons and the two trailers will accommodate 80 passengers. The speed of the train is not great, nor is it desirable that it should be, as passengers ascending the mountain frequently desire to study the scenery at different points as they advance. It is intended that the trip up to the summit shall consume about one hour and 40 minutes. This gives the passengers the opportunity to accustom themselves to the change of atmosphere. A sudden rise to the top of such a mountain is dangerous to many people, but with a slow rise it is estimated that not 1 per cent. of tourists will be unpleasantly affected by the air. The train runs on the maximum gradients of 25 per cent. at a speed of 8 5 kilometres [about five and a half miles] per hour, but even this speed will not be maintained at all seasons of the year. Those suffering from mountain sickness can be let off at almost any place along the line where medical attendance can be obtained."

THE LATEST PHASE.

THE modern cheap magazine or periodical is distinguished by the amount of shady advertisements out of which it makes its profits. In a recent number of a periodical, entitled *Home Chat*, appears the following: "Medicine at half price. For 6d. and stamped addressed envelope, I will give you, in English, a copy of your doctor's prescription, whereby you will save half the cost of dispensing same, and know what you are taking; faithful copies guaranteed.—Templeton, 13, Cobden Road, Brighton." We do not know who Templeton may be but we presume that he is a pharmaceutical chemist. How the mere fact of a prescription being in English will save half the cost of dispensing we do not understand, but we think it gross impertinence of Templeton to try to interfere between a medical man and his patient, neither should we have the slightest confidence in his guarantee.

THE MOTOR-CAR IN MEDICAL PRACTICE

IN continuation of the article on motor cars which we noticed in THE LANCET of Jan. 9th, p. 134, Mr. A. D. Pithie, L.R.C.P., L.R.C.S. Edin., in the *Car* of Jan. 6th gives his experience of the use of a motor in a country practice.

THE RELATIONS OF HOSPITALS AND LOCAL DISPENSARIES.

To the Editors of THE LANCET.

SIRS,—It is a pity that some definite alliance between the hospitals and the dispensaries (private, provident, and eleemosynary) situated in their neighbourhood cannot be negotiated. In the matter of a second opinion, for instance, why should not the hospital staffs act as consultants for the dispensaries while they are on duty at the hospital? At present when the medical officer of a dispensary wants a second opinion on a case he knows he has only the hospital to which he can appeal. But he knows also that if he sends his patient with a note to the hospital the chances are that he will see that patient no more and will receive no reply to his note. Of course, this is not the case if the letter be sent to a personal friend on the staff, but one cannot always be bothering friends. But it will be admitted that to lose sight of interesting cases is annoying, and yet it is the case at present, except in the special circumstance mentioned above. The patients are absorbed into the hospital either as out- or in-patients and no more is heard of them. If matters were properly arranged the hospitals would act as consultants for the poorer practices and the dispensaries would offshoots of the hospitals for the purpose of obtaining local knowledge and thus eliminating those cases for which hospital charity was not required. These are the cases which at present clog the hospital out-patient and casualty departments and cause waste of the funds urgently needed in other directions.

I am, Sirs, yours faithfully,
W. H. KESTEVEN.

A MEDICAL AUTOMOBILE CLUB.

AN automobile club confined to members of the medical profession has just been formed at Newark, U.S.A., under the title of the Physicians' Automobile Club of New Jersey. The club has been organised for social purposes only, although the establishment of a club garage may be decided on later, while it is hoped to secure a reduction in the costs of motor accessories by purchasing these jointly. A feature of the meetings of the club will be discussions of a practical nature on the various parts of the motor car and the methods of taking care of the same.

RACIAL DEGENERATION.

To the Editors of THE LANCET.

SIRS,—Will any of your readers advise me where to obtain [illegible] statistics or notes on the subject of racial degeneration? Such source as army recruiting would be valuable.

I am, Sirs, yours faithfully,
Thornleigh, Swinton, Rotherham, Jan. 10th, 1904. B. C. STEVENS.

During the week marked copies of the following [illegible] have been received: *Coventry Herald, Birmingham [illegible], Reading Mercury, Mining Journal, Local Government [illegible], Liverpool Courier, Westminster Gazette, Pall Mall Gazette, [illegible] News, Irish Times, Nottingham Guardian, Aberdeen Free [illegible] (Weekly), Hertfordshire Mercury, Windsor and Eton [illegible] Standard, South Wales Daily News, Walsall Advertiser, [illegible] Advertiser, &c.*

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

[illegible] *raphs should be* [illegible]" [illegible] *advertising de-* [illegible] *dressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1903, which was completed with the issue of Dec. 26th, were given in THE LANCET of Jan. 2nd.

VOLUMES AND CASES

VOLUMES for the second half of the year 1903 will be ready shortly. Bound in cloth, gilt lettered, price 18*s.*, carriage extra

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

A Lecture
ON
OLD UNREDUCED DISLOCATIONS OF THE SHOULDER-JOINT,
INCLUDING FIVE HITHERTO UNPUBLISHED CASES OF OPERATIVE TREATMENT, IN ONE OF WHICH GOLD PLATE WAS BURIED FOR 40 DAYS.

Delivered in the West London Post-graduate College on Dec. 21st, 1903,

BY C. R. B. KEETLEY, F.R.C.S. ENG.,
SENIOR SURGEON TO THE WEST LONDON HOSPITAL AND LECTURER ON CLINICAL SURGERY IN THE WEST LONDON POST-GRADUATE COLLEGE.

GENTLEMEN,—Dislocation of the shoulder-joint is the commonest of dislocations and one of the most liable to remain unreduced. This liability may be explained in the following way. The joint is thickly covered with both muscle and fat in the middle-aged males who are most liable to this injury, so that when swelling supervenes a wrong or doubtful diagnosis is apt to be made. The patients are not infrequently alcoholic and therefore careless of their persons and dilatory in reporting themselves to their medical attendant or in presenting themselves at hospital. The injury is not always a very painful one. Possibly one reason why it is sometimes confounded with fracture is that it usually is complicated with some minor fracture, especially with fracture of the greater tuberosity of the humerus. We have learnt this from the practice of operating on unreduced dislocations and also from the use of the x rays. The great majority of these dislocations are subcoracoid and it will be remembered that their reduction is usually attempted either by extension combined with leverage obtained by using the surgeon's foot or fist as a fulcrum or else by manipulation, using the attachment of the coraco-humeral ligament to the edge of the glenoid cavity as a fulcrum and often also combining with the manipulation extension applied to the upper end of the arm and at right angles to its long axis so as to prize the head of the humerus from beneath the coracoid or the clavicle. And it is not uncommon to combine with any method direct pressure with the fingers over the head of the humerus with a view to pushing it into the glenoid cavity.

The most justly popular of the manipulation methods is Kocher's and there is no better extension method than that known as Astley Cooper's—namely, with the heel in the axilla. Kocher's method, as is well known, is based mainly on the consideration that the upper and outer part of the capsule, including especially the strong bands which extend from the coracoid process to the humerus on each side of the bicipital groove, remains untorn. In order to relax this the upper arm is rotated strongly outwards. Previously, in order to bring the head of the humerus firmly against the edge of the glenoid, the elbow is pressed against the flank and, in resistant cases, backwards and towards the spine as well. Then the arm is raised in an antero-posterior plane up towards the front of the shoulder. The head of the humerus ought then to have been by these manipulations levered into position on the edge of the glenoid opposite the rent in the capsule and ready to slip into place as soon as the humerus is rotated inwards. Measures like these frequently succeed in old dislocations as well as in new, especially if they are used with skill, patience, and perseverance. (Great force should not be employed on account of its dangers.) Thus Kocher reduced 12 out of 13 dislocations by manipulation. Their age was as follows: one of three weeks, two of five weeks, three of seven weeks, four of three months, and two of four months. Other surgeons do not seem to have been quite so successful, though Kocher's pupil, Oeppi, says that one can reduce an old as easily as a recent dislocation. It is difficult to avoid a slight feeling of scepticism, especially when one has inspected the interior of an old unreduced shoulder-joint. The usually accepted limit for even attempting reduction of dislocated shoulders has long been three months. It is well known that success has occasionally followed attempts on much older cases, but only rarely. And many dangerous accidents have resulted from the employment of even moderate force. No reasonable person can suppose that a very old unreduced dislocation can be freed from its adhesions and from its new capsule, and a place remade for it in the glenoid now firmly adherent to overlying soft tissues and often to fragments of bone without the exercise of force.

SYMPTOMS.

Those of an old unreduced dislocation differ in some points from those of a fresh one. Instead of swelling and effusion of blood there is wasting of the deltoid and of other muscles. The absence of the head of the humerus from the glenoid and its presence elsewhere thus become very obvious. On the other hand, in some old cases the original projection of the elbow from the side becomes lessened, but not in all, at least until a very considerable time has elapsed. In some cases time and exercises increase the range of movement of the displaced shoulder-joint, but in others time diminishes it. The freedom of movement of the scapula on the trunk tends to increase. As a rule there is no difficulty in recognising an old dislocation of the shoulder, because the absence of the head of the humerus from the glenoid can be felt so easily as well as seen. Whether or not there is also a fracture is less easy to determine, but the x rays can be of great assistance. Neither in a skiagram nor even in the course of an open operation is it always possible to be sure whether abnormally placed bone has been chipped off, torn off, or altogether newly formed.

PROGNOSIS.

The longest series of cases of old dislocation of the shoulder treated at one hospital under one surgeon with which I am acquainted is that given by J. Finckh in his admirable account of the experience of Professor Bruns in the Tübingen Clinic. It includes exactly 100 cases. In 27 of these reduction was not attempted and in 73 it was. In nearly two-thirds of these 73 it was successfully effected. Much, of course, depended on the age of the dislocation. After the ninth week failure became usual—there were only two successes out of 16. Up to the ninth week 46 out of 55 were reduced—i.e., 84 per cent.:—

In the 2–3 week were 20 cases, of which 19 were reduced ... ... = 95 per cent.
In the 3–6 week were 24 cases, of which 20 were reduced ... ... = 83 per cent.
In the 6–9 week were 11 cases, of which 7 were reduced . ... = 64 per cent.
} = 84 per cent.

I think these figures give a very just idea of the general prognosis and that Finckh sums up the position well in the following words: "If no complication coexists the prognosis of dislocations two to four weeks old is absolutely favourable, up to the ninth week very good, since up to this point of time nearly four-fifths of all the cases were reduced. Cases of longer duration than nine weeks were only exceptionally reduced without a cutting operation." I will deal with the prognosis of cutting operations when I describe them under the head of treatment.

The non-operative reduction of old dislocations is attended with the same risk of accidents as is that of recent ones. First, as regards anæsthetics, there appears to be a special danger attached to the administration of chloroform to facilitate the reduction of dislocation of the shoulder-joint. Kocher states that Marchand collected 134 deaths from chloroform, of which no less than 11 occurred in reducing dislocations of the shoulder. I seldom or never permit chloroform to be given in such cases myself. In one of the few exceptions I have permitted to this rule for many years the patient was himself a surgeon and had his own way; but in one case in which I was about to attempt reduction of a hip chloroform was given contrary to my wish and there resulted a death from anæsthesia which to the survivors, including myself, was one of the most painful catastrophes I have ever witnessed. The great majority of recent shoulder dislocations and not a few older ones need no anæsthetic at all; and if one is required gas or ether should be given. If the patient struggles when the reduction has commenced one of two courses should be adopted: (1) either the surgeon should proceed without any more anæsthetic at all being administered, hoping to effect the reduction quickly; or else (2) he should desist altogether and the anæsthetist, carefully avoiding all hurry, should patiently and watchfully get the patient well under. I give this advice because deaths from anæsthetics have occurred in the following way. The patient has shown signs of consciousness as soon as the surgeon, commencing to operate, has touched some sensitive tissue or organ. The anæsthetist has then attempted to hurry the patient into a state of profound anæsthesia. The breathing has gone wrong or ceased a second or two before the anæsthetist, whom a long series of successful administrations has made unsuspicious, has realised what has happened. It has then been too late to retrieve the situation. If the breathing stops while strong extension is being used the surgeon should always desist.

Secondly, as regards *risk to vessels*. It should be remembered that serious accidents of this kind have occurred with the use of force described by reliable men like Mr. T. Holmes, for example, as moderate or even as "slight." The Tam O'Shanters and Souter Johnnies who form so large a proportion of these cases are apt to have unsound vessels, as, indeed, are more abstemious people of advanced middle age, and even in the healthiest subjects the adhesions and new fibrous tissue formed around the displaced head of the humerus frequently adhere to the axillary vessels. The great majority of old unreduced dislocations affect persons between the ages of 40 and 60 years. Another remarkable fact about these cases is that even with a perforated axillary artery there may be no loss of radial pulse at the wrist. This was observed both in Holmes's and in Callender's cases. There is also sometimes little or no pulsation of the large axillary swelling which forms and usually keeps increasing and is accompanied by pain in the arm which may become very severe and by the general signs of hæmorrhage, such for example, as pallor and restlessness. Nor is there always a bruit.

Thirdly, with regard to *injury to nerves*, minor nervous troubles such as pins and needles and numbness in the fingers occur sometimes and usually pass away, especially if assisted by rubbing and galvanism. But more serious troubles, including great pain, also occur and used to be regarded as the principal indication for operative measures which then generally took the form of excision of the humeral head. More rarely dislocation of the shoulder occurs in conjunction with such severe injury of the brachial plexus that surgery vainly attempts to afford a remedy. These terrible cases of injury to the brachial plexus or its roots more frequently, however, follow falls on the shoulder which do *not* cause dislocation. Dislocations of the shoulder, though they often are caused by falls on the shoulder, are more frequently the result of falls on the elbow or the hand. Even complete motor and sensory paralysis of the arm complicating dislocation of the shoulder is sometimes seen to pass off without operative treatment.

With regard to *complication by fracture*, the most common is that in which the greater tuberosity is broken off; the next most common is fracture of the surgical or anatomical neck. Less frequent are fractures of the edge of the glenoid fossa. I cannot give any trustworthy figures. The use of the x rays and the practice of operative reduction are showing that old figures bearing on these points are erroneous. Great œdema of the arm is sometimes seen.

With regard to the prognosis in cases of dislocation of the shoulder which remain unreduced, if observed for some years they are sometimes seen to improve wonderfully in the matter of usefulness. Not that the degree of all-round mobility of the new and abnormally placed joint becomes at all comparable to that of the old but it increases up to a certain point and is supplemented by increased mobility of the scapula. Nevertheless, the majority of unreduced dislocations of the shoulder are seen, even after many months, to inflict on their subjects great disability, especially in fulfilling the functions of the toilette. When nerves are compressed, pain and even paralyses further complicate the case and may be incurable without operation.

PATHOLOGY.

Of the changes in the relations of the bones I could not hope to equal, much less to improve upon, the description given by Sir William Flower in Holmes's "System of Surgery," second edition, vol. ii., p 813. Writing of fresh dislocations of the common or subcoracoid variety he says: "The head of the humerus lies on the anterior surface of the neck of the scapula, immediately below the coracoid process, in front of, internal to, and rather lower than, its normal situation. That part of the anatomical neck which separates the articular surface from the great tuberosity rests upon the anterior edge of the glenoid fossa. The subscapular muscle is raised from the neck of the scapula and stretched over the front of, or above, the head of the humerus. The muscles from the back of the scapula are drawn tightly across the glenoid fossa or one or more of them may be ruptured or detached from the bone. A portion or the whole of the greater tuberosity is frequently separated, when it may be drawn into the glenoid fossa by the action of the muscles inserted into it or may be retained in connexion with the humerus by the periosteum or the capsular ligament. The long tendon of the biceps is rarely, if ever, injured. (Footnote.—As Dr Hamilton has recently asserted that, contrary to what has been affirmed by Sir Astley Cooper, the tendon of the long head of the biceps is often broken asunder or detached completely from its insertion (op. cit., p. 535) I may mention that the statement in the text is founded on examination of numerous specimens and reports of dissections)." The truth is that the long head of the biceps is occasionally but exceptionally torn from its attachment. In all the 44 cases given in brief abstract in Reerink's collection of unreduced dislocations treated by arthrotomy or by excision this accident is not once noted. But it is significant that in the only two cases of which a *full* anatomical description is given by the same author (quoting from Jössel) the biceps tendon was torn from the glenoid cavity in one case and ended as a small fibrous band in the bicipital groove. The biceps tendon was intact in all the five dislocated shoulder-joints I have operated on myself. "The muscles that descend from the coracoid process to the humerus are stretched by the projection of the head of the bone forwards and the great vessels and nerves are displaced inwards Occasionally the circumflex nerve is pressed upon to such an extent as to cause paralysis of the deltoid muscle," &c.

In old unreduced cases "in process of time a new shallow socket is formed upon the anterior surface of the neck of the scapula, partly by absorption of old bone and partly by deposit of new around its edge." In subcoracoid dislocations "the new cavity is formed more or less at the expense of the anterior portion of the glenoid fossa, which is gradually worn away, so that in some cases the original socket is finally almost entirely lost. A corresponding change takes place in the head of the humerus; where it rests upon the edge of the glenoid fossa absorption occurs, so that a groove is excavated, usually between the articular head and the great tuberosity. With continued friction this increases in size simultaneously with the change in the scapula; the two accommodate themselves to each other and utimately the head of the latter bone presents a double articular surface, separated by a vertical ridge, the posterior portion being part of the old glenoid cavity, the anterior the newly formed socket. These respectively articulate with the two sides of a wide groove placed vertically on the head of the humerus, and thus a rude kind of joint, which allows of a certain amount of motion, is formed." "The under surface of the coracoid process, especially near its tip, is almost always found smooth and eburnated, having entered into the formation of the new articulation."

The above changes in the glenoid and in the humeral head do not take place in intracoracoid dislocations, and in subglenoid cases the scapular new articular surface is formed "on the upper part of the anterior border of the inferior costa of the scapula, encroaching considerably upon the lower and anterior part of the glenoid fossa" (Flower).

This does not by any means end the account of the salient anatomical features of an old unreduced dislocation of the shoulder. The new joint, as seen in an open operation, is not so much the result of absorption as of new formation. In or near its edges, or parts of them, is found new bone, often in the form of separate osteophytes. The cavity is deepened by fibrous tissue which surrounds the head of the humerus, forming a new capsule and closing the hole in the old capsule. This fibrous tissue is partly due to degeneration of the muscles which stretch over the head of the humerus and is partly derived from such fragments of capsule, of fat, of cellular tissue, of fascia, and of aponeurosis as lie in contact with the dislocated head. In a few weeks it becomes more and more impossible to distinguish these various components, which, so to speak, fuse together. A thin layer of cartilage may form on the new joint surface of the scapula, but in the glenoid fossa the cartilage either altogether disappears or leaves only a few scattered "islands" behind. The new capsule has a glistening interior surface as if lined with synovial membrane, which apparently secretes a rather scanty synovial or pseudo-synovial fluid. The glenoid fossa is filled with tissue, sometimes formed by adhesions of the outer part of the capsule and of the external rotator muscles and sometimes partly of these and partly of bone torn from the greater tuberosity of the humerus. The head of the humerus besides being altered in the manner already related is often greatly changed as a sequence of fractures of the greater tuberosity or of the anatomical or of the surgical neck. This change is usually increased by the formation of callus, of osteophytes, and of ossifications in the attached muscles. In one case it was described as resembling in shape the upper extremity of the femur. In one of my cases it was greatly increased in the transverse diameter.

TREATMENT.

The choice lies between, on the one hand, endeavouring to make the best of this new joint by exercises, massage, and electricity, and on the other attempting to effect reduction by means of (1) manipulation or extension; (2) open incision; and (3) excision. Subcutaneous division of soft parts

otic operation.

were reported

atomical neck

followed by an endeavour to place the upper end of the shaft into the glenoid has been recommended. I should be loth to try this mode in the case of the shoulder because I have seen it so utterly fail in the case of dislocation of the head of the radius at the elbow. After a mere division of a bone the fragments, even when carefully displaced, lie alongside each other and tend to unite ultimately. Passive movements are usually too painful in such cases to be used effectually.

The attempt at reduction without cutting.—This may reasonably be tried any time up to the end of the fourth month except in old people with atheromatous arteries. First of all Kocher's method should be applied (1) without anæsthesia and (2) with ether or with chloride of ethyl. As it is *not* involuntary muscular contraction which makes the difficulty the anæsthetic is given to prevent pain and need not always be pushed to the most profound depth. Remember what has already been written above about the danger of chloroform in this class of cases. Kocher's method having failed, extension and circumduction may be tried. The means of counter-extension should not press upon the folds of the axilla. To prevent this Skey invented his knob. In the absence of such an instrument some large firm pad should be placed in the axilla and the counter extending force made to bear upon it. The extension should be made in four directions: (1) extension in the line of the axis of the humerus downwards; (2) counter extension upwards; (3) from the upper part of the humerus just below the insertion of the pectoralis major, outwards; and (4) counter-extension to force 3, from the side of the chest across the thorax. If a machine is used my fracture extension machine will do, *but a dynamometer must be employed.* The degree of force justifiable would depend on the age and development of the patient. I think 100 pounds is the outside which should

by pulling one end of a simple loop or by cutting a cord with a sharp knife, which should lie open and close at hand. Guérin reported a case in which the forearm was torn off. After the forcible extension and rotation a second trial of Kocher's method may be made. There should be no hurry. Many accidents have followed such attempts at reduction, even when reported as having been of gentle character.

Fracture of the surgical neck of the humerus is not very frequent. It occurred in four out of the 73 cases in which reduction was attempted in von Bruns's clinic. Of these four,

n a case recorded by

he reduced the upper

A false joint some-

follows. The functional result may then be good. A false joint followed a case of Albert's in which the surgical neck broke and he pulled the head into the glenoid with two hooks. This was, of course, an open operation. The shaft of the humerus has been broken in employing Kocher's method. Limited paralyses, e.g. of the fingers, are sometimes caused but they are usually only temporary. However, main cords of the brachial plexus are said to have been torn. Flaubert reports a case.

The structure especially endangered is the axillary artery. Many cases have been collected by Flaubert, Malgaigne, Callender, Le Fort, Willard, Marchand, Körte, and Stimson. In Stimson's collection of 44 cases the axillary vein alone was ruptured in three (Froriep, Price, and Hailey), although he thinks the last one doubtful, and the artery and vein together in two (Platner and Baum). In most of the others the axillary artery or one of its branches was injured, but in some the source of the hæmorrhage remains uncertain. The upper was always the part of the artery injured. In a minority of the cases only a small opening was found and that on the anterior wall of the artery (see, e.g., Callender's case, op. cit). In more than half the cases the dislocation was recent (less than three weeks old). Sometimes it is certainly caused by the dislocation and not by the reduction. Often great force had been applied. As I have already written Callender and *Holmes say the force used in their* cases was moderate or even slight. Stimson says that "the accident is most to be apprehended when the elbow is raised in abduction to the height of the shoulder, or is carried, as in Callender's case, across the chest and face in a wide movement of circumduction; and for this reason, that in these movements the dislocated head of the bone is turned downward into the axilla and the vessels which lie upon its inner side are pressed down before it and put upon the stretch, while those branches which run almost directly outward, the subscapular and circumflex, and are fixed to the tissues amid which they branch, are directly and forcibly elongated."

The symptoms of rupture of the axillary artery vary. Sometimes, as in Callender and Holmes's cases, a large diffuse swelling appears quickly in the axilla and grows to an alarming size, discolouration also appearing, but no pulsation and little or no bruit, while even the radial pulse may be little affected. In other cases the ordinary signs of aneurysm, pulsation and bruit, are present. Some cases have been so chronic and the tumour so small that aneurysm has

have been incised. Rupture of

est a serious accident, but the

e other authors mentioned, being

mainly

It is re

any ope

the accident to amount to 70 per cent.

In a case of rupture of the axillary artery associated with dislocation of the shoulder I should be disposed (1) to place a temporary ligature on the subclavian; (2) to clear blood and clots out of the axilla, to tie any branch of the axillary found torn or the axillary itself if it was torn in two or nearly in two, but to leave it untied if there was merely a small oval hole in it (as occurred in 5 cases out of 32); this small hole I would close by suture if that operation proved easy; in any circumstances I should pack the axilla carefully with antiseptic or aseptic gauze. (3) If the patient's condition was not of the best, I should immediately inject neutral saline solution either subcutaneously or into one of the veins exposed by the operation. Owing to the everyday practice of clearing out glands, surgeons nowadays are much more at home in operating on the axilla than were the surgeons, great men as some of them were, who reported the cases collected by Stimson.

After the operation careful bandaging would be, of course, essential and should fix without compressing the whole arm and hand to the trunk. If the dislocation still required reduction, and especially if attempts at reduction had been made and failed, it would probably be best to defer trying to reduce it. But all would depend on the age and condition of the patient and on the age of the dislocation.

Other modes of using extension besides (1) manual force, (2) the old-fashioned pulleys and (3) machine extension are (4) continuous elastic extension and (5) the use of Stimson's perforated couch. Continuous elastic extension is mentioned by Ceppi as having been used by Legros, Th. Anger, and A. Després. The use of a dilatable indiarubber bag in the

the side.

reduction had taken place. Stimson's couch is perforated to permit the arm to pass through A weight of ten pounds is attached to the hand which, of course, hangs down beneath the couch. Its dragging gradually effects reduction. This is obviously a very simple plan, not alarming to the patient, and, I should think, not likely to be very painful.

Two other forms of diabetic bread are very useful—casoid bread and casoid meal bread.[2] Both are practically free from starch and sugar and are thoroughly reliable. These preparations are composed chiefly of casein. Chemical analysis (by E. J Parry, B.Sc) shows that the casoid meal bread contains 38·9 per cent. of proteids and 13·9 per cent. of fat. Some diabetic patients prefer the protene bread, some the casoid meal bread, and many like the casoid bread best. I think the patient may be safely allowed to take the one he likes best or to combine them in any way as all three specimens are quite satisfactory.

Aleuronat and cocoanut cakes are also of service.[3] They may be prepared in the following manner. Two ounces of desiccated cocoanut powder are mixed with a little water containing a small quantity of German yeast. The mass is then formed into a paste and this is kept for half an hour or longer in a warm place. The small amount of sugar contained in the cocoanut is almost entirely decomposed by the fermentation produced by the yeast and the cocoanut paste becomes spongy. Two ounces of aleuronat, one egg beaten up, and a small quantity of water, in which a little saccharin or saxin has been dissolved, are now added to the cocoanut and the whole is well mixed until a paste is formed. This is spread out on a tin and divided into cakes which are baked for 20 or 30 minutes. In a case of diabetes of medium severity I found that the daily sugar excretion was reduced by 2000 grains and the daily amount of urine by 80 ounces when aleuronat and cocoanut biscuits were given in place of white bread. Almond or cocoanut biscuits can also be prepared according to the directions just given, aleuronat being omitted and only cocoanut powder or almond flour being used.

Milk contains about 4 per cent of objectionable milk sugar, but it also contains a large percentage of valuable fat and albumin. Cream contains less milk sugar and about seven times the amount of fat; it may be allowed in all forms of diabetes. In some cases of diabetes ordinary milk does not increase the sugar excretion; in such cases it may be allowed freely. In other cases milk increases the sugar in the urine and in these cases a substitute is desirable. I have prepared an artificial milk, practically free from sugar, which may be taken in unlimited quantities by diabetic patients in all forms of the disease. Four tablespoonfuls of cream are added to a pint of water and well mixed. The mixture is allowed to stand in a cool place. At the end of 12 hours the fat of the cream will have floated to the surface. (It can be skimmed off with a teaspoon and on examination it will be found practically free from milk sugar which will remain dissolved in the pint of water.) The cream fat is skimmed off from the surface of the water in the first vessel and then placed in another vessel, and to it are added water, the white of an egg, and a little salt (and a trace of saccharin if desired) A palatable artificial milk can thus be prepared which is practically free from milk sugar. (The egg albumen may be omitted or added according to the patient's preference.) A sugar-free milk (prepared according to the directions given by Dr. R. Hutchison) can also be obtained,[4] which is of much service to diabetic patients; it may be diluted with water or soda-water.

As regards beverages those which are free or almost free from carbohydrates can be taken (indicated in the diet sheet shown at the lecture). I believe that ordinary beer and many non-alcoholic forms of beer are injurious Also it is desirable that the amount of alcohol in the form of spirits should be very limited, especially in the milder forms of the disease.

Many patients suffering from the milder forms of diabetes derive much benefit from a visit to Carlsbad or Neuenahr. It is difficult to estimate what share the drinking of the waters of these spas may have had in the causation of improvement. But it appears probable, from the observations of continental physicians, that the drinking of the waters at the spas whilst *hot* from the spring has some effect in diminishing the sugar excretion. In the severe forms of diabetes a visit to these spas is useless and often the long journey has a most injurious effect on the patient.

TREATMENT BY DRUGS.

Whilst it must be admitted that we have no sp
remedy for diabetes I believe that several drugs have
tinctly beneficial action. I think I have demonstrated c
that two drugs at least—salicylate of sodium and as
given separately or combined—have a definite acti
diminishing the sugar excretion in *certain* cases of dia
of the milder forms. These conclusions are based on
observations made on cases of diabetes in the wards c
Ancoats Hospital. The patients have first been kept fc
or 14 days or longer on ordinary hospital diet or on
similar to that which they were taking before admiss
the hospital. During this period no drug has been
except a few minims of peppermint water and the
excretion has been determined daily. It has thus
possible to estimate the constant sugar excretion apart
drug treatment. Then for a period of two or three we
longer salicylate of sodium or aspirin has been given.
sugar excretion has diminished. The drug has been
discontinued and peppermint water given (the diet
kept unaltered). The sugar excretion has increased. Si
observations have been repeated on the same patient,
times on many occasions, with the result that whils
salicylate of sodium or aspirin was being taken the
excretion has diminished. I have published records of
cases in 1901 and 1902[5] Since these dates I have had si
favourable results in other cases of the mild form
diabetes in hospital and private practice. (Charts sho
the good effects of these drugs on the sugar excretion
shown at the lecture. In some of the cases the lecture
indebted to Dr. F. G. Hack and previous house physicia
the Ancoats Hospital for assistance in the sugar estimati
The diminution of the sugar excretion has not been d
the occurrence of any complications and the patient
felt quite well whilst taking the drugs.

Neither sodium salicylate nor aspirin is a specific
diabetes. I have never found any definite diminutic
the sugar excretion under the action of these drugs in
most severe forms of the disease; also in some of
milder forms they have not had any marked effect; b
other cases of the milder forms I believe I have obta
conclusive evidence of their beneficial action. As reg
the mode of administration, I have usually given soc
salicylate in peppermint water, commencing with
grains three times a day and increasing up to 15 gr

to which a drop of lemon juice has been added. Soda-w
or alkalies should *not* be taken just after the aspirin pow
otherwise the drug would be liable to decompose in
stomach and cause gastric symptoms. Some patients
the sodium salicylate better than aspirin; others
aspirin better. This latter drug is less liable to cause to
symptoms in large doses. Sometimes cases are met w
in which one of these drugs can be taken but not the ot
Recently, I have often combined the two drugs with g
results, giving sodium salicylate up to 15 grains three
four times a day and one powder of aspirin, 15 grains,
night. Whenever the two drugs are given it is import
to commence with small doses and steadily to increase
quantity, watching for bad effects.

By a restricted diet, by the use of casoid or prote
bread, sugar-free milk, &c., along with the administrat
of salicylates or aspirin, often satisfactory results can
obtained in the milder forms of diabetes. (See chart
the end of this article.) The salicylates and aspirin are
service especially, because they often enable satisfacto
results to be obtained without the employment of an ab
lutely rigid diet. Cases are, however, sometimes met w
in which salicylate and aspirin cannot be taken owing
the disagreeable symptoms that they produce even in sm
doses.

Many other drugs have been used in the treatment
diabetes, and it is probable that opium, morphia, codei
sumbul, uranium nitrate, arsenic, and antipyrin have
certain cases some beneficial effect. An objection to th
first three drugs is their constipating action, and this

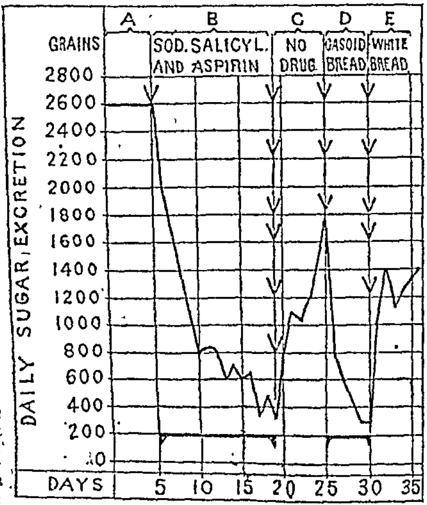
[3] Aleuronat is a vegetable albumin, first recommended for diabetic patients by Professor W. Ebstein. Recently he has employed other forms of vegetable albumin, ergon, roborat (recommended by Loewy and Pickardt), and casein (recommended by Schreiber). See Handbuch der praktischen Medicin: Ebstein and Schwalbe. Stuttgart, 1901.

[4] This milk can be obtained from Messrs. Clay, Paget, and Co., 23, Ebury-street, Eaton-square, London, S W.

[5] Brit. Med. Jour., March 30th, 1901, and Dec. 27th, 1902.

especially undesirable in the most severe forms of the disease, since constipation appears to predispose to the onset of coma. It is important, therefore, when these drugs are given that care should be taken to keep the bowels regular In the most severe forms of diabetes, in which the urine gives a deep brownish-red colouration with perchloride of iron, I believe the alkaline treatment, bicarbonate of sodium in large doses, is of some service in postponing the onset of coma The dose should be steadily increased up to two, three, or four drachms or more daily. The bicarbonate is best taken in frequent doses in soda-water or milk. It is very important not to produce gastric disturbances by the sodium bicarbonate, but it is remarkable how well these large doses are usually taken by diabetic patients.

Chart showing Influence of Salicylates and Aspirin, and also of a Rigid Diet, on the Sugar Excretion in Diabetes.



A, Period of 20 days five only represented on the chart. Ordinary hospital diet, including usual amount of white bread and milk but excluding potatoes and sugar, which had not been taken for several years. Peppermint water one drachm three times a day. Sugar excretion practically stationary, average 2690 grains daily. On the twentieth day sugar excretion 2626 grains. B, Diet kept the same. Sodium salicylate 15 grains four times a day + aspirin 15 grain [illegible] grains. ON CERTAIN NEW METHODS OF BLOOD EXAMINATION WITH SOME INDICATIONS OF THEIR CLINICAL IMPORTANCE.

By A. E. WRIGHT, M.D Dub.,
LATE PROFESSOR OF PATHOLOGY, ARMY MEDICAL SCHOOL, NETLEY; PATHOLOGIST TO ST. MARY'S HOSPITAL, PADDINGTON, W.

An exhaustive examination of the blood is impossible with the present methods of collecting blood from the patient. When the blood is collected into tubes or capsules and is allowed to clot there the serum alone becomes available for examination. When blood films only are prepared we are confined to a histological examination of the corpuscular elements. When, lastly, blood is drawn off into a diluting fluid for the enumeration of the corpuscles we are tied down to this particular examination. These limitations can be transcended by drawing off the blood into a calibrated capsule charged with a measured quantity of citrate of soda solution. The blood thus prevented from clotting furnishes for our examination all the different blood-elements: red corpuscles, white corpuscles, blood-platelets, and plasma. The red corpuscles are furnished in a form in which they can be employed indifferently for histological examination and for quantitative estimation. Even more than this is achieved in the case of the white corpuscles. These are furnished in a form which admits not only of their histological examination and enumeration but also of the measurement of the phagocytic power which accrues to them in the plasma or as the case may be in any other medium which may have been substituted for this.

Method of collecting blood into a calibrated capsule charged with a measured volume of citrate of soda solution.—The capsule with recurved limb already figured by me in previous papers[1] is the form of capsule best adapted to the procedure described below. For the purpose here in question it is charged with a quantum of citrate of soda such as suffices to keep the blood which is received into it liquid. The capsule is further furnished with a fiduciary mark to indicate the point to which it is to be filled in with blood. The calibration of the capsule and the filling in of the measured charge of citrate of soda solution can be accurately and expeditiously carried out by the aid of a pair of automatic pipettes. The respective cubic capacities of these are so adjusted as to stand to each other in the quantitative relation which is to obtain between the blood and the citrate of soda solution.

Method of making the automatic pipettes.—The smaller of the two automatic pipettes is made as described in a previous paper in The Lancet[2] The procedure is varied only in the respect that 50 cubic millimetres, more or less, in lieu of 5 cubic millimetres, of mercury are employed and in the respect that the orifice of the pipette is in the course of construction drawn out into a point in the flame of a peep light. The larger automatic pipette which serves for calibrating the blood capsule is made in the following way.

A piece of glass tubing is taken in hand. It is drawn out into a [illegible] stem and this is again drawn out into a sharp point. [illegible] matic pipette a volume of mercury [illegible] 00 cubic millimetres and accurately [illegible] is introduced into the neck of the [illegible] pass down some little distance into [illegible] 1) is [illegible] the [illegible] the [illegible] the [illegible] the [illegible] it in such a manner as to bring the [illegible] indicated by A in Fig. 2 The fiduciary mark into [illegible] is by the aid of the flame of a peep light narrow tube thus obtained [illegible] the fiduciary mark into a tube of such fineness as [illegible] out at the fiduciary [illegible] This done [illegible] ng back the [illegible] d to place a [illegible] he mercury [illegible] ng out the [illegible] The [illegible] the mark B and breaking it off [illegible] y. across just below the neck. Into this covering tube we insert the measuring tube from above and draw the capillary stem down through the neck. Finally, we apply heat in such a manner as to melt the sealing-wax and to make an air-tight joint (Fig. 4).

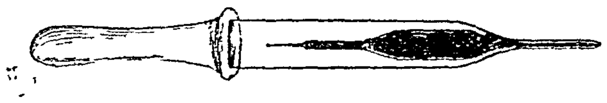
Fig. 4.



Method of calibrating the blood capsule and charging it with the citrate of soda solution.—Having broken off the points of both the recurved and of the straight limbs of the blood capsule the larger automatic pipette is taken in hand. Placing a rubber teat over the upper end and making pressure upon this a negative pressure is established in the interior. The orifice of the automatic pipette is now inserted into a reservoir of mercury and the metal is allowed to flow in until the bulb is full. When this has been accomplished the point of the pipette is withdrawn from the mercury and is brought in contact with the orifice of the recurved limb of the blood capsule (Fig. 5). By pressing upon the teat the mercury is in an almost automatic manner transferred to the capsule. The mercury in the blood capsule is shaken together and the capsule is tilted in such a manner as to bring a column of mercury back to the neighbourhood of the orifice through which it was introduced. The height at which the mercury is standing in the recurved limb and in the barrel of the capsule is now marked off with a glass writing pencil. The smaller automatic pipette is now taken in hand (Fig. 6). A negative pressure having been established in its interior a small bead of mercury is drawn into the orifice of the tube. The point of the pipette is then transferred from the vessel of mercury to a vessel containing a 4 per cent. citrate of soda solution made up in physiological salt solution. On relaxing the pressure on the teat the pipette sucks up the citrate of soda solution until the bead of mercury which is carried up in front of the column of fluid arrives at the terminal hair-fine tube and there establishes a block which prevents any further intake (Fig. 6). The point of the pipette is now applied to the orifice of the recurved limb, pressure is made on to the teat, and the watery fluid transfers itself to the capsule in an even more automatic manner than was the case with the mercury. The charged capsule may either be immediately employed or its ends may be sealed and it may be put aside till required.

Fig. 5.

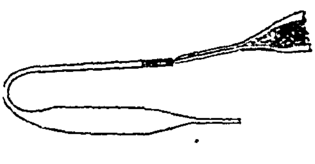


Fig. 6.

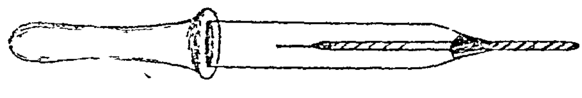

Method of filling in blood from the finger.—The extremities of the capsule having been broken off a prick is made in the side of the finger with a hypodermic needle. A handkerchief is then wound round the digit from above downwards in such a manner as to render the extremity of the finger definitely turgid. Pressure is now made upon the pulp and the blood as it emerges from the prick is received into the recurved limb of the capsule to con mingle there with the citrate of soda solutio When the blood has reached the fiduciary ma the upper end of the capsule is warmed such a manner as to rarefy the contained ai The upper limb is then immediately sealed u As soon as the glass has cooled and the co traction of the air has drawn up the blo from the recurved limb into the body of tl capsule, this last is shaken to effect thoroug mixture of the citrate of soda and blood.

Appearance of the blood as it settles down in the capsule.—The advantage of the method begins to exhibit itself with a very few minutes. Figs. 7, 8, 9, which are taken fro actual specimens, exhibit the appearances of three differe bloods. Fig. 8 represents a blood drawn from a patie suffering from Bright's disease. The volume of the co puscular sediment is approximately normal. The plasm has a milky aspect. Fig. 7 represents blood taken fr a patient the subject of extreme anæmia.[3] The chara teristic feature of the blood is the small volume of t corpuscular sediment. Fig. 9 represents blood drawn fro a leucocythæmic patient.[4] The exaggerated depth of t layer of white corpuscles is the salient feature. A notic able feature also is the reduction in the red corpuscl Equally characteristic is the appearance of the blood in cas of jaundice. Here, and the same holds true also in so cases where active hæmolysis is going on, the plasma definitely yellow.

Fig. 7.

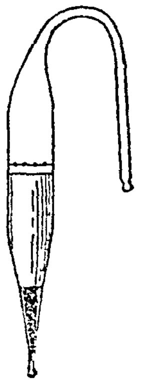

Fig. 8.

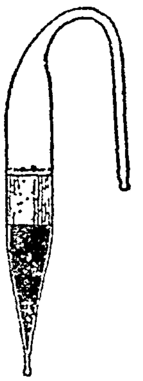

Fig. 9.

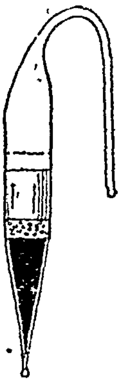

Further procedures.—The further procedures may undertaken at any convenient time after the withdrawal the blood. Opportunity is thus afforded for the conveyan of blood to the laboratory or, if need arises, for its tran mission by the post. In the following I will confine mys to describing certain new developments in connexion wi the methods of blood examination.

Quantitative estimation of the corpuscular elements.—T defects of the hæmocytometric method are well understoo They are summed up in the fact that the results of a blo count may deviate from the truth to practically an unlimit extent if the calibration of the apparatus is at fault or if t operator is either unwary or wanting in skill. A furth regrettable feature in the hæmocytometrical method is t unsuitability of the method for purposes of demonstratio The enumerator alone can take personal cognisance of t results. The only alternative which at present offers is t measurement of the corpuscles by the hæmokrit. While t principle of this method has met with general approval i particular application in the hæmokrit is open to obje tion on the ground that it involves recourse to a highl geared centrifuge and manipulation of somewhat delica apparatus. In point of fact, nothing of this kind necessary. The volumetric measurement of the corpuscles can be carried out in a perfectly effective manner by the simple procedure of filling in citrated blood into a capillary tube which has been marked off into a series of divisions of equal cubic capacity. In the case where the result of the measurement is required with the minimum of delay the graduated stem of the capillary pipette may be broken off short at the neck and the hand centrifuge may be called into use. Ordinarily the blood may simply be left to sediment overnight. By the next morning sedimentation will be practically complete and the number of volume divisions occupied by the corpuscles can be read off at a glance. As indicated in Figs. 11 and 12 the number of volumes of corpuscles corresponding to ten divisions of the undiluted blood may range from one or below one in cases of very extreme anæmia to six divisions (or a little less) in the normal adult male. The following is a method which allows of the division of a capillary pipette in an expeditious manner into any desired number of divisions of equal cubic capacity.

---

[3] The number of red corpuscles in this patient's blood, as determin by the hæmocytometer, was 650 000 per cubic millimetre.

[4] The number of leucocytes in this patient's blood—as determin by the hæmocytometer—was just over 500,000 per cubic millimet The diagnosis of leucocythæmia was arrived at in the course of a f minutes by the appearance of the blood as it settled in the capsule.

FIG. 10.

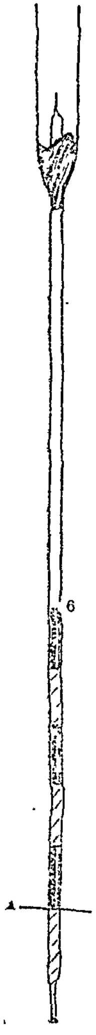

FIG. 11.

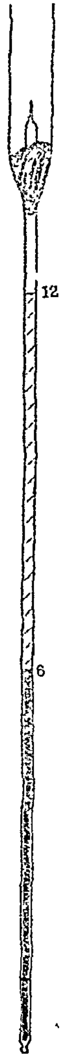

FIG. 12.

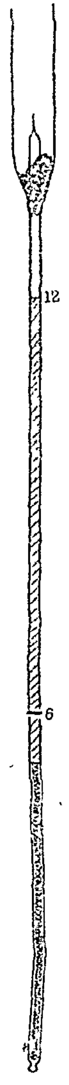
FIG. 13.



Instructions for dividing the stem of a capillary pipette into any desired number of divisions of equal cubic capacity.—Take in hand a piece of glass tubing drawn out into a capillary stem and draw it out below into a fine point. The capillary pipette thus obtained may be employed just as it is, or it may if desired be formed into a throttled pipette similar to the pipettes shown in Figs. 10 to 13. In any case fit a tightly fitting rubber teat upon the upper end of the pipette and inscribe a mark upon the stem at a distance from the orifice corresponding to about one-twelfth of its total length. Making pressure on the teat and holding the pipette at a considerable angle to the vertical thrust the pointed end below the surface of some mercury which has been placed in a watch glass and which has been covered in with water. Now let the mercury run up and fill the tube up to the fiduciary mark A, Fig. 10, then push the point of the pipette out through the mercury into the water and let a similar volume of this last pass up into the tube. Withdrawing again the point of the pipette under the cover of the mercury, go through the whole manœuvre again until the tube has, as is shown in Fig. 10 been filled in with a series of six alternate volumes of water and mercury. This done withdraw the point of the pipette from the watch glass and mark off with a pencil a series of six divisions. Having marked off these six (which will be all that will be required for the measurement of the corpuscular sediment), bring the series of six alternate volumes of mercury and salt solution further up into the tube, and *taking off in this measurement from the* sixth division inscribe upon the upper end of the capillary stem a fiduciary mark corresponding to the twelfth division.

Instructions for filling in the graduated capillary pipette with citrated blood.—Shake up first the contents of the blood capsule in such a way as to bring into suspension the corpuscles which may have settled down. Then fitting a teat to the graduated pipette draw up into it from the capsule exactly 12 volumes of citrated blood. Dealing as we are with a five sixths dilution of the blood these 12 divisions will correspond to 10 of the undiluted blood. After rectifying the position of the column of blood in the tube, seal up the pointed extremity of the tube in the flame of a peep light and—unless in [illegible] is to be employed—place the [illegible] a rack. Figs 11, 12, and 13 [illegible] furnished by filling in in this [illegible] pipettes respectively with normal blood and with blood from a case of extreme anæmia and a case of Bright's disease.

Preparation of blood films from corpuscular sediment.—When we desire to proceed to the histological examination of the corpuscles we may with advantage make our films either from the corpuscular sediment generally or as the case may be *from a particular stratum of the corpuscular* sediment, diluting in each case with such amount of plasma as may be convenient. This method of procedure enables us even in the case of the most extreme anæmias—where this is by the ordinary technique impossible—to concentrate in the microscopic field a sufficiently large number of the corpuscular elements to make an effective histological examination. The procedure promises further advantages, for judging from the fact that it is possible by diluting the blood with an equal bulk of physiological salt solution to obtain the white corpuscles separate from the red it will probably be found possible by an appropriate dilution of the blood to bring together into a particular stratum of the sediment the particular elements which happen to constitute the object of our search. By this process of levigation it may, for instance, prove possible to bring together, as the case may be, red corpuscles charged with malaria parasites, nucleated red corpuscles, and free living parasitic elements of all kinds.

Method of preparing slides for the reception of blood films.—In connexion with the histological examination of the blood passing reference may appropriately be made to, perhaps, the most important factor involved in the preparation of a blood film. This factor is the preliminary treatment of the slide. Popular prejudice to the contrary notwithstanding, it will be found that the really important thing in connexion with the slide is to secure that its surface shall be rough. The polishing of the surface and the defective adherence between the blood and the slide which results from it furnish the opportunity for the piling up of the corpuscles one upon the other under the influence of the surface tension of the fluid. The polishing of the slide is, in other words, directly responsible for the patchiness of the ordinary blood film. I find it to be a wise procedure to boil all slides in strong caustic potash until their surface has become definitely hazy. It is hardly necessary to point out that such haziness, dependent as it is upon inequalities of the surface, altogether disappears when the oil or, as the case may be, the Canada balsam is placed upon the slide.

Estimation of the quantity of blood platelets.—Milkiness of the blood fluids is a characteristic feature of the blood in many cases of diabetes and Bright's disease. It is met with also as a temporary and less conspicuous phenomenon in the healthy in the course of active digestion. This condition of the blood—it is commonly misnamed lipæmia—appears in point of fact to depend upon an extraordinary excess of blood platelets[4] Two points of interest with regard to these may be noted—first, that blood which contains platelets in quantities sufficient to render the plasma absolutely milky is not more coagulable than ordinary blood; and secondly, that it may be possible—and this has been suggested to me by my friend, Captain Stewart R. Douglas, I.M.S.—to proceed to the enumeration of the platelets in citrated plasma. This suggestion has its justification in the circumstance that the platelets do not in the case of citrated blood run together into clumps and they remain in suspension indefinitely after the settlement of the corpuscles.

Quantitative estimation of the amount of albuminous substance in the plasma or serum.—We shall remain in ignorance with respect to the causes of many œdemas and with regard to the proper method of treating these conditions just so long as we neglect in dealing with these disorders to investigate the character of the circulating blood fluid and of the lymph. What is perhaps most urgently required for such an investigation is a method of determining the content of the blood in albuminous substances. Until a better method shall have been elaborated the following will, I think, render useful service.

Principle of the method.—The method here proposed aims at the determination of the degree of dilution to which the blood may be subjected before it loses the property of coagulating into a stiff jelly when subjected to a temperature just below that of boiling water. The apparatus required is a capillary tube, a little mercury, water at a temperature just below boiling point, and a glass-cutting knife, or in default of this a pair of small bone forceps. The material subjected to examination may be any sufficiently concentrated albuminous fluid. In particular it may be the plasma, serum, blister fluid, or pericardial, pleuritic, or ascitic effusion.

Procedure.—The first step in the procedure is to make an appropriate series of dilutions of the fluid. In dealing with blood I have commonly employed in addition to the undiluted serum dilutions of $\frac{5}{6}$ths, $\frac{4}{6}$ths, $\frac{3}{6}$ths, $\frac{2}{6}$ths, and $\frac{1}{6}$th. A series consisting of undiluted serum and in association with this $\frac{7}{8}$ths, $\frac{6}{8}$ths, $\frac{5}{8}$ths, $\frac{4}{8}$ths, and $\frac{3}{8}$ths dilutions of serum would be more appropriate.

The dilutions first spoken of are made as follows. The stem of a capillary pipette is, by the method already described above, divided into six equal divisions. By the aid of a rubber teat this tube is filled with serum up to the fifth division. One volume of physiological salt solution is then aspirated into the tube and the whole is blown out and mixed upon a glass slide. Four volumes of this mixture are re-aspirated into the tube and an additional volume of diluting fluid is added. This furnishes a dilution of $\frac{4}{6}$ths. After it has been mixed upon the slide three volumes of the mixture are re-aspirated and again an additional volume of salt solution is added, furnishing a $\frac{3}{6}$ths dilution. Of this, two volumes are re-aspirated into the tube and a third volume of diluting fluid is added. This furnishes a $\frac{2}{6}$ths dilution. Lastly one volume of this dilution is re-aspirated and it is diluted with one volume of salt solution furnishing a dilution of $\frac{1}{6}$th.

The alternative series of dilutions above referred to would be prepared either on exactly the same principle as above or as follows. By taking three volumes of serum and adding one of diluting fluid, then taking two of the $\frac{3}{4}$ths serum and one of diluting fluid, and lastly, by taking one of $\frac{2}{4}$ths serum and one of diluting fluid we obtain a series of dilutions corresponding to $\frac{3}{4}$ths, $\frac{2}{4}$ths, and $\frac{1}{4}$th serum. Taking this preliminary series of dilutions and, in addition, undiluted serum we proceed to obtain the intermediate dilutions as follows. Mixture of equal volumes of undiluted serum and $\frac{3}{4}$ths serum would give us $\frac{7}{8}$ths serum mixture of equal volumes of $\frac{3}{4}$ths serum and $\frac{2}{4}$ths serum would give us $\frac{5}{8}$ths serum, and mixture of equal volumes of $\frac{2}{4}$ths serum and $\frac{1}{4}$th serum would give us $\frac{3}{8}$ths serum.

Having obtained the appropriate series of dilutions our next step is to draw up these progressive dilutions into a capillary inspissation tube and to separate them off one from the other. Our graduated tube may do service as our inspissation tube or we may employ for this purpose any other capillary tube which has been drawn out at its extremity into a sharp point. In either case we proceed as follows. We draw up first one volume of the highest dilution, then carefully avoiding, here and at all subsequent stages of the procedure, the intrusion of bubbles of air we draw into the point of our pipette a pellet of mercury of sufficient size to divide off securely from the next dilution of serum. We in this way take up into the tube the whole series of dilutions of serum, dividing off in each case by mercury. This process accomplished we seal the point of the tube in the flame, taking care as we do so not to include any appreciable quantity of air. We now plunge our inspissation tube into a vessel of water which has just begun to cool down after having been brought to the boil. After waiting from three to four minutes we withdraw our tube from the water and fit to its upper end a rubber teat in the collapsed condition. Leaving the negative pressure thus generated to do its work uncontrolled and taking the tube into one hand and a bone forceps into the other we proceed to snip off the point of the pipette. By so doing we ascertain whether the clot which has been formed in the undiluted serum is or is not competent to resist the pressure of the atmosphere. If it holds fast we snip away the capillary stem piece by piece. As our successive lines of section traverse the successive mercury pellets we take note in each case that we are passing from one dilution of the serum to the other. Finally, we arrive at the point where the coagula proximal to the line of section yield to the negative pressure. When this happens and the column of clotted fluid is carried up into the expanded end of the pipette we take note of the fact that we have exceeded the limits of dilution in which the serum when coagulated by heat offers effectual resistance to the pressure of the atmosphere. Tested by the above method the blood of normal male adults gives a resistant clot in a maximum dilution of four sixths to three-sixths.

Remarks on the above method.—While the method described above makes no pretence to absolute accuracy it will be found, when put to the test, by making a series of successive estimations of any sample of blood, to yield very concordant results within the range of calibre which is dictated, on the one hand, by considerations of the amount of serum ordinarily available and, on the other hand, by the limit imposed by the considerations that the capillary tube must not be so fine as to offer sensible resistance to the passage of fluids nor be so weak as to be incapable of resisting ordinary strains. In connexion with the clinical application of the method it may be interesting here to call attention to the information which was furnished by the method in a case of œdema of the feet which was when first seen supposed to be referable to double femoral thrombosis supervening upon typhoid fever. In this case the method of examination here in question revealed that the content of the blood in albuminous substances was reduced to the point at which the clot formed by heating the undiluted serum was quite incompetent to resist the pressure of the atmosphere. The same held true of the lymph obtained by the application of a blister. In view of the unlikelihood of thrombosis occurring under such conditions, and further, in view of the negative result of Widal's test, the treatment by citric acid which had been inaugurated with a view to limiting the extension of the presumed clot was abandoned and magnesium sulphate was administered with a view to concentrating the blood. Under this treatment the œdema rapidly disappeared and the serum yielded on heating a resistant clot.

Estimation of the content of the plasma in fibrinogen—In concluding this paper reference may be made to the circumstance that an estimate of the amount of fibrinogen in the plasma can be formed by the very simple device of heating citrated plasma in a tube up to a temperature of 60° C The plasma in hæmophilia when examined by this method yields, as compared with the normal plasma, a notably diminished volume of fibrinogen.

[4] The identification of the particulate matter in milky plasma with blood platelets is warranted by the characteristic staining reaction obtained with Leishman's stain.

INTRAPERITONEAL RUPTURE OF THE BLADDER IN A GIRL, AGED FIVE YEARS,

WITH SEPARATION OF THE RIGHT OS PUBIS AT ITS EPIPHYSEAL LINES; ABDOMINAL SECTION; SUTURING OF THE BLADDER; RECOVERY.

BY H. BETHAM ROBINSON, M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO, AND SURGEON IN CHARGE OF THE THROAT DEPARTMENT, ETC., AT, ST. THOMAS'S HOSPITAL; SURGEON TO THE EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL.

IN *September, 1901, an interesting* summary of all the recorded cases of traumatic rupture of the bladder appeared by Alexander in the *Annals of Surgery* and previously to this statistical papers dealing with the same subject had been published by Kerr, in the *Annals of Surgery*, vol. xvii , 1893, and by Miles, in the Transactions of the Royal Medical and Chirurgical Society, vol. xxvii., 1895. From a perusal of these papers it will be of interest that the following case is the youngest that has been operated on (according to available records) up to date; there have been two cases of children seven years of age and one of nine years of age.

Traumatic rupture of the bladder, whether extraperitoneal or intraperitoneal, may exist alone or very frequently is attended by damage to the pelvic girdle; if the rent is extraperitoneal the broken pelvis has probably played a part in causing the wound, whereas in the intraperitoneal form it may be only an accidental associate due to the same crushing force: an accepted explanation in the latter is that it may be the crowding back of a full bladder on the sharp lumbo-sacral angle. In this particular case the bladder had been distended and from the tender years of the child was abdominal in position. Although the bladder wound in this case had an accompanying damage to the pelvis the latter did not cause it; the wheel passed obliquely over the abdomen from left to right, causing the bladder rent to be also oblique and lower on the same side as the fractured pelvis.

On March 11th, 1903, the child was playing in the road when she was knocked down by a cart, the wheel passing over her abdomen. This occurred at 2 P.M. and at 4 30 she was brought to the hospital and admitted. She was pale, restless, and very collapsed, with a feeble pulse of 128 and respirations 28, with grunting expiration. Her temperature was 97° F. Breathing was almost entirely thoracic in character but the upper part of the abdomen moved fairly; the lower part was rigid, moved very little on respiration, and was tender even to gentle palpation. On light percussion in the flanks there was evidence of the presence of a small quantity of intraperitoneal fluid and the *whole abdomen* appeared to be considerably distended. The child complained of pain and kept calling out that she wanted to pass urine but on trial she was quite unable to do so. The catheter withdrew about a couple of teaspoonfuls of nearly pure blood with a urinous odour. On manipulation of the pelvis soft crepitus could be obtained which was due to diastasis of the right os pubis at its epiphyseal lines. At 9.30 P.M., the immediate shock having passed off, the abdomen was opened by a three inch incision in the mid-line and there was not found any blood extravasation in the cellular tissue. On incising the peritoneum a collapsed bladder was found which was brought up into the wound. On the superior surface was a rather oblique rent running from *one obliterated* hypogastric artery to the other side through which the mucous membrance prolapsed and out of which a few drops of bloody urine could be squeezed; on the left side the rent came right up to the lateral reflexion of the peritoneum. The flanks contained some free urine which was mopped out with sponges and the peritoneum was then cleansed with sponges dipped in normal saline solution The rent in the bladder was carefully sutured with fine silk; the interrupted stitches were inserted after Lembert's method and avoided the mucous membrane. Beyond the single row two or three extra stitches were put in where there seemed a weak spot. The abdominal incision was then closed except in its central part through which a gauze drain wrapped in green protective was passed down to the wound in the bladder. A soft catheter was placed in the bladder *viâ* the urethra. The child had some additional shock after the operation but speedily rallied when in bed. Her legs were kept tied together and no other fixation was used for the pelvis. On the 12th the drain was changed and there was a considerable amount of fluid in the dressings with a urinous odour. On the 15th the wound had been dressed daily and there was now no suspicion of any urine on the dressings. The drain was removed and a small gauze drain was put in the gap in the abdominal incision. The child's condition was first class and there was free passage of urine through the catheter which was still retained. On the 18th the drain was removed altogether and on the 19th the catheter was taken out. For some days there was some incontinence of urine which gradually passed off. On April 4th the child developed some broncho pneumonia which all cleared up at the end of a week. She remained in hospital until May 4th and was discharged walking quite well, without any difference in the length of the limbs and with perfect control of the bladder.

The history of the accident in this case and the early symptoms pointed plainly to the probable diagnosis which the passage of the catheter confirmed. Such tests as inflation with air or injecting fluid into the bladder were not utilised for, in the first place, they were unnecessary to establish the diagnosis and, in the second place, such procedures are likely to do much more harm than good by causing greater diffusion of the escaped bladder contents over the peritoneum. Such a procedure can only be of academic interest and, as Alexander says, having the idea that the bladder is *ruptured, at once operate and if on exposing the front of the* bladder no damage is found then open the peritoneum and search for the rent. There is nothing particular to comment on the operation. No special stitching of the mucous membrane was done; a single layer of fine silk Lembert interrupted sutures, fortified by a few more beyond, was used for the sero-muscular coat. There was no peritonitis but the case was fortunately operated on early. After cleansing the peritoneal surface I thought it safer to use a small gauze drain for a short time; it can do no harm and it may be of great service should the stitching unfortunately not hold.

The last point is one that has always been debateable—namely, the after-treatment of the sutured bladder. Excluding from the question putting a tube into the bladder suprapubically, it is a moot point whether there should be drainage per urethram or regular catherisation. Alexander has shown that of 39 cases there was an infinitesimal advantage gained by continued drainage; one thing is quite certain, both from the patient's and surgeon's standpoint, the drainage is much simpler.

Upper Wimpole-street, W.

A CASE OF ACUTE SULPHONAL POISONING.

BY ALFRED E. HIND, F.R.C.S. ENG.

THE patient, a single woman, aged 27 years, had been under treatment suffering from melancholia. She had previously been five years in an asylum. She was now living with her parents while arrangements were being made for sending her to another asylum. I was called at 9 A.M. on Dec. 17th, 1903, by her father who stated that he was unable to wake his daughter and that he suspected that she had taken three bottles of sulphonal, each containing 25 tablets, five grains in each, with the exception of two tablets found in the bedroom. In all she had taken 365 grains. On arrival I found the patient comatose and unable to be roused. There was no cyanosis. She was slightly pale The pulse was 80 and feeble, the respirations were 15, and the temperature was 98° F. The corneal reflex, the knee-jerks, and the radial reflex were absent. The pupils had medium contraction and reacted sluggishly. She had spoken rationally a few words early that morning. The bowels had opened on the previous day. The patient had been in the habit of taking sulphonal for insomnia and had threatened suicide. The stomach was washed out with about a gallon of warm water which returned quite clear. A large enema of soap and water was given and retained. The urine was drawn off by catheter; it was clear and abundant. Half a pint of hot coffee was passed by a tube into the stomach and one-thirtieth of a grain of strychnine and one-fiftieth of a grain of digitalin were injected hypodermically. The patient was visited again in the evening; her condition was unchanged except that the corneal reflex had returned. The catheter drew off about three pints of clear urine. The bowels had not acted. On the 18th she was again visited. She had roused sufficiently in the night to swallow some coffee. Three pints of urine were drawn off by catheter and a pint of hot milk with two minims of croton oil was passed by a tube into the stomach. The bowels had not opened. The patient was surrounded by hot-water bottles. In the evening the bowels had not opened and her condition was unchanged. The pulse was 100, the respirations were 15, and the temperature was 98°. Hot milk and three minims of croton oil were given by a tube which was almost immediately followed by vomiting. Some of the gastric contents being inhaled necessitated energetic treatment to restore breathing and to relieve cyanosis, under which treatment the patient roused considerably but soon relapsed into lethargy. An enema of soap with five minims of croton oil resulted in a small evacuation, chiefly enema, but some fæcal matter was present. Again three pints of urine were drawn off and a hypodermic injection of digitalin and strychnine was given as before. The patient was visited at 9 P.M.; half a pint of urine was drawn off. Her condition was unchanged. On the 19th at 10 A.M. she was cyanosed. The respirations were 30, the pulse was 112, and the temperature was 103·5°. No physical signs of pneumonia were detected but her condition was probably affected by the inhalation of the gastric contents on the previous day. She was rather more collapsed and still unconscious. She had had a nutrient enema of egg and milk which she had retained. Hypodermic injection was given as before. At 1 P.M. the respirations were 40, the pulse was 130, and the temperature was 103°. One pint of urine was drawn off. One-thirtieth of a grain of strychnine was given hypodermically. At 6.30 P.M. the respirations were 44, the pulse was 130, and the temperature was 103·8°. Three quarters of a pint of urine were drawn off. One-thirtieth of a grain of strychnine and one-sixtieth of a grain of digitalin were again given. The patient showed a slight return of consciousness. She had retained the nutrient enema of milk and egg and had spoken a few inarticulate words during the day. After the hypodermic injection the respirations fell to 30, the pulse to 112, and the patient had a better appearance. On the 20th the respirations were 32, the pulse was 112, and the temperature was 103·8°. One pint of urine was drawn off. The cardiac action was much stronger. The radial reflex and the knee-jerks had returned. The patient now appeared to notice her surroundings. The bowels had opened slightly. The nutrient enemata were retained. A certain sweet chloroform-like odour had been noticed in the breaths since the first visit and lately also in the urine. The bladder remained in an atonic state and air entered after the urine was expelled by pressure on the abdomen. At 6.30 P.M. the pulse was 90, the respirations were 20, and the temperature was 100°. She was slightly restless and had been trying to get out of bed. She had passed urine under her and the bowels had opened slightly. She had spoken incoherently during the day at intervals. On the 21st she had a restless night and was more conscious. The pulse was 80, the respirations were 20, and the temperature was 99°. The catheter drew off one and a half pints of urine. The bowels had opened slightly. She retained the nutrient enemata and had taken fluids by the mouth. At 6 P.M. the pulse was 80, the respirations were 25, and the temperature was 99·4°. She was steadily regaining consciousness. Her speech was staccato and cerebration was slow. The catheter drew off three quarters of a pint of urine. On the 22nd the pulse was 80, the temperature was 98·4°, and the respirations were 15. She had been upon the stool but the bowels had not opened. She still took food by the mouth and had passed urine normally. She volunteered the information that she swallowed the above amount of sulphonal at 11 o'clock on the evening of the 16th with suicidal intent. On the 23rd the pulse was 80, the respirations were 15, and the temperature was 99·4°. The bowels had opened. The catheter drew off three-quarters of a pint of urine; she was menstruating. She was much quieter and taking food fairly by the mouth. Four drachms of sulphate of magnesium were given in the morning and repeated in the evening. On the 24th she was still improving. The bowels had opened twice. She passed urine on the stool; the catheter drew off four ounces only. She was taking food better. The pulse was 80 and the temperature was 98·4°. She slept well. Speech and cerebration were very little altered. On the 25th she had markedly improved. Her speech was clear and cerebration was most active. The bowels were well opened; urine was passed naturally. She was taking food much better and she slept well. From this day her convalescence was uninterrupted as regards the sulphonal poisoning and on Jan. 2nd she was sent to an asylum.

As regards the treatment of the case, with no definite data to go on, and a strong presumption of her having taken sulphonal, washing out the stomach seemed to be the right step, although, as it subsequently turned out, it was perhaps of little use as some 12 hours had already elapsed. Although the large enemata were retained they doubtless helped to eliminate a large amount of the poison by the kidney, and as for medicine, strychnine and digitalin seemed to be the only drugs indicated. The inhalation of the stomach contents was an unfortunate incident which, however, did not seem to affect the case very seriously, although septic pneumonia at one time threatened to complicate a most intractable case. Coma, absence of the reflexes mentioned above, including atony of the bladder and the bowel, were the most striking features in the case. The accidental inhalation was no doubt due to this condition also. The heart sounds were very feeble, more so than the pulse would suggest. Her condition at the first visit gave very little clue to the cause and it was only on the strong presumption of what had happened that sulphonal poisoning was diagnosed. Her recovery, however, was complete and happened more or less abruptly on the eighth day. No anorexia or constipation remained. Her mental condition also remained unaffected. Although when first seen her condition appeared to be critical, if not even hopeless, in the light of her subsequent recovery one is apt to regard the danger incurred with less fear. Other cases reported appear to have been followed by protracted evil effects and to have recovered very slowly. Examination of the urine showed a slight trace of albumin, no sugar, 4·5 per cent. of urea, and no blood. It was clear, light-coloured, and of specific gravity 1030; it had no smoky tint. The absence of a spectroscope precluded the test for hæmatoporphyrin. I should be glad to have suggestions as to any antidote for sulphonal if such exist.

Jersey.

A CASE OF ACUTE TRAUMATIC CHOLECYSTITIS.

BY FRED. J. SMITH, M.D. OXON., F.R.C.P. LOND.,
PHYSICIAN TO THE LONDON HOSPITAL;
AND
C. W. MANSELL MOULLIN, F.R.C.S. ENG.,
SENIOR SURGEON TO THE LONDON HOSPITAL.

A MAN, aged 59 years, was walking to business on Dec. 29th, 1903, when he slipped on some ice and fell. The history of how he fell is not quite clear, though he himself asserted that it was "all his length on his right side." He complained at the time of some pain but went to business and seemed no worse for the accident until Jan. 3rd, 1904, when he complained to his wife that his side hurt him, but he did not take much notice of it. On the 5th his bowels acted as usual in the morning and again at about 2 and 4 o'clock in the afternoon. (The sequel suggests that these actions were melænic.) Soon after the second action he was sick and in a little while was seized with a severe pain in the abdomen. He was shortly afterwards seen by Dr. Mowbray Henderson who administered morphia. The pain continued all that night sufficiently severely to keep him awake. He vomited on the morning of the 6th and again on the following morning but not subsequently. His bowels never acted after the loose motions on the 5th notwithstanding the administration of two enemata on the 6th and two on the 7th; the second enema on the latter date brought away a little fæcal matter. On the 8th the abdomen began to swell and Dr. Henderson asked me (F. J. S.) to see him at 1 P.M. as a case of intestinal obstruction. I found the patient lying in bed quite quiet and sensible; his face was very congested, almost blue, like the face of bad "bronchitis with emphysema." The pulse was somewhat full, 117 per minute, with rather *plus* tension if anything and not the thready pulse of either asphyxia or peritonitis. The abdomen was full, round, and somewhat distended, offering no good opportunity for discovering much by palpation, but there was very marked tenderness just below the liver in the area corresponding to the gall-bladder. Percussion here also caused much pain but revealed no dulness—in fact, to sum up, one had a picture of intestinal obstruction without much guide to its seat or causation. I accordingly arranged to see him again in the evening with Mr. C W. Mansell Moullin. I found the condition unchanged except that the pulse was now 120 and had lost its tension and fulness. His temperature had, by the way, since the 5th been hovering between 99° and 101° F.

Mr. Moullin decided to operate, though he could not frame a very definite diagnosis. We discussed the question of slight laceration of the liver or the gall-bladder, but rejected it from the absence of jaundice and from its general improbability. He opened the abdomen in the middle line and found—absolutely nothing, except one small omental hæmorrhage, so he then opened the cæcum by another small incision and fixed a catheter in the ileum. During the 36 hours that the patient survived a certain amount of black fæces—melæna—escaped from this tube, but he got weaker and died at about 8 A M. on the 10th.

The necropsy was performed at 3.30 P.M. on the same day. The lungs and the kidneys were quite sound and the heart too, except for marked degeneration of the aorta (the valves were quite sound and the muscle was good). The intestines, too, were sound and there was no peritonitis observable by the naked eye, though as the intestines were fuller than usual I suspect there was a loss of tone in the peritoneal coat. The liver was a trifle fatty but otherwise healthy, and the only pathological change was with the gall-bladder. This externally was seen to be intensely inflamed, of a brown colour, and with patches of lymph scattered over it It was moderately distended and the connective tissue round it was dark in colour and evidently not healthy. On cutting [illegible] due to what was very [illegible] ltered by decomposi- [illegible] or less necrotic and [illegible] the soaking. There were no gall-stones and no appearance whatever even faintly suggestive of a growth.

In my experience such a case is unique and I think it must be at any rate very rare. An interesting question arises as regards the precise cause of the paralytic obstruction of the bowel, whether it was due to a nerve influence through the bruising of the gall-bladder or whether [illegible] n the absence of [illegible] I should incline [illegible] dmitted that the examination was carried out very soon after death.

Another interesting point is how the gall-bladder came to be the only viscus that was bruised There was no external bruising of the skin over it, so that considering the nature of the accident—a simple fall on a level road—it is not likely that the injury was due to direct violence, and yet the fact seems very difficult to explain upon any other hypothesis, as the gall-bladder is such a yielding viscus.

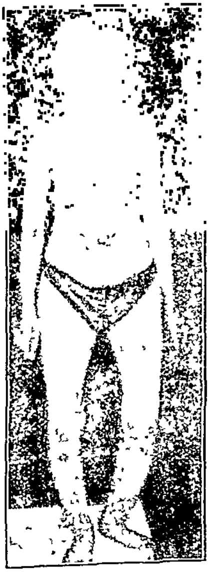
TWO CASES OF OSTEITIS DEFORMANS IN ONE FAMILY.

By WALTER J. KILNER, B.A., M.B. Cantab, M R C P. Lond.

THE rarity of this disease is a sufficient excuse for giving a short account of two cases lately seen by me. They are brother and sister who have both passed middle age.

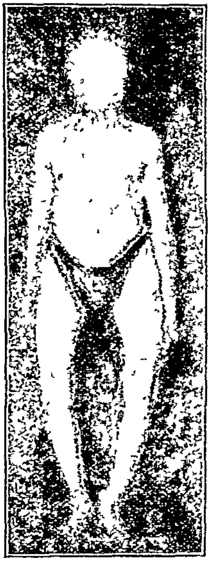
CASE 1.—The patient is a married woman, 69 years of age, who has had three sons, all of whom are alive and healthy, and two daughters, one being married with three children, and the other one having died during childhood. Until five years ago she enjoyed excellent health, her only illnesses being a severe miscarriage 30 years ago and an attack of sciatica seven or eight years ago. During her first pregnancy her left leg swelled and was dusky in colour, the condition being, as far as I can glean, due to varicose veins. At the present time the superficial veins of that leg are varicose. Previously to the last five years her figure was erect and she could not have measured less than 5 feet 7 inches—most likely an inch more. This is only approximate as she was considerably taller than a friend who is 5 feet 6½ inches. Now, however, her height is only 5 feet 1½ inches when she draws herself upright, which she is able to do only for a very short time Her present illness began insidiously with what were thought to be "rheumatic pains." As nearly as she can remember the parts affected were attacked in the following order. the left leg, the right leg, the knees, and the soles of the feet; some short time afterwards the spine, first in the lumbar region, then between the shoulders, and last of all the right arm, the shoulders, the hips, and the clavicles. The pain was more or less continuous with nocturnal exacerbations, when the hips and legs were the seats of the greatest pain. Frequently she had very severe attacks lasting some hours or even a day or two. She had lost flesh, being now very thin instead of weighing 12 stones When undressed she presents a remarkable figure (see Fig 1). There is marked kyphosis, the back of her head following the same curve as the spine while she is standing at rest. She is, however, able to raise her head, but it soon drops again. The shape of her head is peculiar and the cranial bones are enlarged, although she does not seem to have noticed this herself as the thickening has proceeded gradually. The lumbar curve of the spine is exaggerated but this is to a great extent masked by its being sunk between two ridges of flesh. There is no lateral curvature Her clavicles are thick and enlarged irregularly Her ribs seem to yield to pressure more than they ought if quite healthy; however, their shape remains unaltered Her right arm is not so straight as her left, nor can she extend it fully at the elbow-joint. Her pelvis seems to be unaffected. The most marked deformity is in her thighs and her legs, the former outwards and forwards, the latter having similar curves, only the forward one being more marked, especially in the left leg All the bones of the thighs and the legs are thickened irregularly but not all to the same extent Taking the left tibia as an example, on March 3rd the whole bone was enlarged with indurated patches on the upper and lower thirds. These swellings did not include the whole circumference but were on the anterior and outer surfaces They were diffuse with no

FIG. 1.



Female figure

FIG. 2.



Male figure.

perceptible line of demarcation and were intensely tender to the touch. Their appearance was coincident with the exacerbation of pain. Seemingly there was no increase of temperature. After a variable time they gradually disappeared, sometimes leaving no appreciable permanent enlargement. As a rule the skin over the inflamed patches remains unaltered. I have not noticed any of the swellings raised more than a quarter of an inch, while they may be two or more inches in length. Before they become visible the surface of the bone becomes abnormally tender, which I attribute to the periosteum becoming affected before the bone itself. The muscles of the thighs are wasted and flabby and the same may be said of the gluteal muscles, the left side hanging considerably below the level of the right. When lying down with her knees touching there is a space of more than two inches between the thighs. It is only with great difficulty that she can balance herself when she stands with her feet together. When seen sideways she looks as if she must fall forwards. Her gait is a waddle.

For the last two or three years she has been very subject to attacks of bronchitis and is now rarely without a cough. Her heart is healthy but there are signs of atheromatous arteries. Her urine has a specific gravity of 1021 with a trace of albumin; there is no sugar, albuminose, or excess of phosphates; it is slightly acid. Under the microscope only oxalate of calcium crystals and a few epithelial cells were to be seen.

On March 3rd I ordered a mixture of five minims of liquor arsenicalis with five grains of calcium lactophosphate to be taken three times a day, also an embrocation of methyl salicylate in linimentum opii. On the 18th the pain had been less intense except once when she was kept awake the whole night by its severity. On May 2nd she reported herself improved as her acute attacks of pain were not so frequent or so severe. However, she had had swelling and pain in the hand which had left the joints of the thumb and the forefinger of the left hand in a condition similar to the after-effects of an attack of chronic arthritis. On the 16th her right leg had become more painful than the left for the last few days. There was an inflamed spot on the centre of the tibia. I ordered ten grains each of salicin and phenacetin to be taken when the pain was excessive. On June 24th it was stated that the powders had given relief but she had only had to take them twice. Her medicine was altered to ten minims of tinctura belladonnæ, five minims of liquor arsenicalis, and 15 grains of potassii bromidum three times a day.

When I was examining the patient she informed me that her brother was getting bandy legged and could walk only with difficulty. As he was unable to come to town I went and saw him on May 1st.

Case 2.—The patient is aged 60 years. He is a broad-shouldered, cheerful-looking man, a typical, weather-beaten agricultural labourer, with a stoop and very curved legs, looking prematurely old for his years. Formerly he was 5 feet 9 inches in his stockings and quite straight, but at the present time he is six inches shorter. He says that "his deformity is stationary," but his niece wrote to her aunt (Case 1) in April that his legs were getting more bent and again in August that he was worse and that it was quite painful to see him walk. Formerly he was a sawyer and he attributes the bending of his legs to his occupation. His family, ten in number, are all strong and healthy. For 12 years he suffered greatly from pain in his abdomen and in 1898 entered St. Thomas's Hospital where he remained three months without benefit; then he went to St. Mary's Hospital where a few days after admission laparotomy was performed by Mr. H. S. Collier. The pylorus was found to be adherent to the lower surface of the liver. Since the operation he has been quite free from pain. About that time he began to suffer from what he calls "rheumatic pains" in his lower extremities. The pain was more severe in his hips and thighs and the left side was worse than the right. There is one spot just above the inner condyle of the left femur where the pain has been more severe and continuous than any other place. This part remains thickened and tender. The pain in the hips has been greater than in his legs. He gets very tired upon the least exertion and then his legs and ankles ache, especially at night time. Following in sequence his spine was next affected, first in the cervical and upper dorsal and then in the lumbar regions. Afterwards the shoulders and arms were attacked but the pain was never very acute here. At the present time his thighs and hips are the only places which are very painful. After his prolonged suffering from his abdominal trouble he makes light of his present ailment. Without his clothes his figure is peculiar (see Fig. 2), being emaciated but broadly built in the trunk, with proportionally long legs. His head protrudes forwards but it does not droop. The lumbar curvature of the spine is certainly increased. His pelvis is unaltered in shape and does not seem to be affected in any way. There is no lateral curvature of the spine. His thighs present an odd appearance, being wasted, flattened out laterally, and very narrow from front to back. The femurs are curved outwards and forwards, the former being in excess of the latter. The angle they make with the pelvis gives the idea that the weight of the trunk has pressed down the femurs in such a manner that their necks, instead of having a downward inclination to the shafts, have become almost horizontal. The broadest part of the trunk, instead of being at the intertrochanteric line, is quite one and a half inches lower down. The tibia and fibula are curved laterally and forwards, similar to the femurs but not to the same extent. All the bones feel irregular from local thickening, but the most manifest enlargement is just over the internal condyle of the left femur. The left limb is more distorted than the right. The bones of the head have not enlarged, as he can wear the same cap that he wore seven years ago. His clavicles are very prominent and enlarged more than his employment can properly account for. There is no change in his arms. His heart is enlarged, the apex being half an inch to the left of the mammary line and two and a half inches below. There are a prolonged first sound at the base and a loud rasping systolic murmur at the apex. Some of his arteries are atheromatous.

The first of these two cases is as typical a one as can be found, while the second lacks one important symptom of osteitis deformans, the enlargement of the cranial bones, but in other respects his, too, is quite typical. When taken in conjunction with the first there can be no doubt but that brother and sister are suffering from the same disease. These I believe to be the first cases on record where two persons in the same family have been attacked by this complaint. The disease in each of them began insidiously and almost simultaneously; although the sister is nine years the elder yet the brother is constitutionally older. The progress of the complaint is faster in the woman. There is not the slightest reason to suspect that either of them has suffered from syphilis. They have lived at a distance from each other for 40 years and the conditions of life in which they have been placed have been very different. The sister has been comfortably off in London and has suffered no real privations, and until lately has enjoyed excellent health. On the other hand, her brother has had his constitution undermined by ill-health and must have endured considerable hardships, being only a labourer in an agricultural village, either unable to work or at the most capable of undertaking very light jobs. We may conclude from this that neither climatic influences nor the mode of living has had any influence in the causation of this illness. As far as I can make out there is no history of injury, rheumatism, or nervous complaint to account for it. Certainly the woman suffered from sciatica but it was only for a short time and there was a considerable period of good health intervening before this disease showed itself. The first complaint either of the patients made of rheumatism was coincident with the commencement of their present condition and the pain seems to have been the very first symptom noticed and this was at first vague and afterwards became more localised.

There is one important point which has to be considered, Is osteitis deformans a general disease with the bone affection secondary, or are the bones affected primarily and alone? Case 1 alone would point to a general dyscrasia, as her health began to fail coincidently with the appearance of the rheumatic pains and she became liable to attacks of bronchitis and at the same time lost flesh rapidly. At first her walking powers were not diminished but they gradually lessened as the deformity of the legs increased. Strange, however, that she had no idea of the extent of her deformity until she accidentally saw herself in a looking glass when she was very horrified by her appearance. Her attacks of bronchitis seem to be entirely independent of any exacerbation of bone mischief. When her blood was examined under the microscope there was nothing abnormal to be found although it coagulated very quickly and it would not flow from a prick on the finger as easily as it would in a healthy person. With regard to the second case the disease began when the sufferer was prostrated from a purely mechanical malady. When relief was given by an operation his health improved and he has remained well, although he has never become strong and continues to be unable to work on account of his physical infirmity and the pain produced by it. If the first of these cases stood alone there could hardly be any doubt about the disease being a constitutional one. In the second, however, any fresh systemic disturbance could not be well marked owing to its being implanted upon a man already debilitated by prolonged ill-health. His regaining health up to a certain point could be no reason why the disease with him should not be constitutional. Moreover, the fact that two persons in the same family were affected by the same complaint would point to a systemic rather than a local origin.

The treatment in these cases is eminently unsatisfactory, as little or nothing can be done except to build up the general health and to alleviate pain.

Ladbroke grove, W.

A CASE OF TOTAL EXTIRPATION OF THE PROSTATE.

By G. P. NEWBOLT, F.R.C.S. Eng.,
HONORARY SURGEON AND DEAN OF CLINICAL SCHOOL, ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

A MAN, aged 69½ years, was admitted to the Royal Southern Hospital on April 15th last, suffering from retention of urine. His urinary trouble first began five years previously when an attack of retention necessitated the use of an instrument and during the last four years he had led a catheter life. He had to get up at night in order to relieve himself and had had several bad attacks of retention. On April 13th he was unable to pass his soft catheter, and on the 15th he was admitted to hospital with a greatly distended bladder and a false passage from which he was bleeding freely. The bladder was aspirated above the pubes and four hours later a silver instrument was passed. After this the bladder was washed out twice daily, but the passage of the catheter caused him much pain and usually drew blood. On the 24th I saw him and passed a full sized silver prostatic catheter into his bladder; he had a large, soft, moveable prostate easily made out per rectum and bilaterally enlarged. The urine was acid, 1020, and contained blood and pus. On May 10th the patient's condition and the state of his urine having improved I determined to perform suprapubic prostatectomy. He was placed under chloroform and his bladder having been distended with ten ounces of boric lotion I opened the organ above the pubes and on introducing my left index finger at once felt a large prostatic tumour which resembled the uterus in shape with the cervix pointing upwards and backwards. Having scraped through the mucous membrane on the left side of the growth with my index finger nail I was able to enucleate speedily the gland on that side below and from behind the triangular ligament. After spending some five minutes in trying to clear it from the urethra I tore the latter across on the vesical side of the triangular ligament and proceeded to free the right portion. This was more difficult and it was necessary to use scissors in order to free the under and upper portions of the right lobe from the base of the bladder. The growth was then seized with forceps and delivered through the suprapubic wound. Whilst operating the prostate was pushed up from the rectum by the fingers of a colleague. There was some hæmorrhage which was controlled by boric lotion at a temperature of 110° F. A large rubber tube was put in the suprapubic wound and the rest of the incision was brought together with silkworm gut. There was some shock after the operation, from which the patient speedily rallied. The whole proceeding took 23 minutes from the first incision until the wound was sutured.

The after-history of the case is as follows: On the next morning the patient's pulse and temperature were normal. The tube was removed from above the pubes in 48 hours and the bladder was irrigated daily through a soft catheter in the urethra. On the 20th, ten days after operation, I passed a full-sized silver catheter into the bladder and he passed a little urine the right way when his bowels acted on the night before. On June 8th he went home, the wound had closed and he passed urine freely three or four times in the day and once at night. He had an attack of eczema due to the irritation of the urine about the wound, but this speedily cleared up. Two weeks after his return home he had an attack of bronchitis when the wound opened and remained so for a fortnight when it healed soundly. He is now in good health, passes urine freely, and is quite comfortable. The prostate, which was entire, weighed five and three quarter ounces. The ejaculatory ducts were torn across and show well in the specimen. A very thin partition was felt between the rectum and the bladder after removal, but the gap left rapidly contracted. Microscopically the growth was fibro-adenoma. The operation so ably advocated by Freyer seems to be a most valuable one in suitable cases.

Liverpool.

A CASE OF VERONAL POISONING.

By G. FERNANDEZ M. CLARKE, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A. Lond.

THE following case may be of interest to the readers of THE LANCET.

At midday on Dec. 13th, 1903, I was telephoned for to see a woman who, from the message I received, was evidently suffering from narcotic poisoning. On arriving at the house I found my patient in what appeared to be a sound sleep. The breathing was deep and slightly stertorous; the pulse was slow but regular; the pupils reacted to light; and the temperature was normal. With some difficulty she could be aroused but relapsed immediately into her former state of semi-coma. The history which I obtained from her friends was that the patient's age was 19 years; she had been married only a few months and seemed to be very happy; she had had a "touch of the sun" when in Jersey, after which she had been subject to several hysterical attacks varying in intensity, and to the best of their knowledge she had not taken any drugs. With this information I decided not to resort to any drastic measures but to content myself with treating the symptoms. As time went on the symptoms gradually subsided and by midnight I was able to learn from her that she had taken something to make her sleep but of what character that something was she absolutely refused to tell me. It was not until the next morning that I became acquainted with the drug in question when I received from her husband a box of veronal cachets, each containing eight grains, which had been found in her room. I saw her again the same day, when she had apparently quite recovered, having slept soundly throughout the previous night. On the 16th an erythematous rash appeared all over the body. There was a great amount of irritation of the skin, especially of the face which presente
was little or no elevation
passed off in the course of
lotions. On the 21st I w
whom I found suffering
tenderness in the right mastoid region with enlargement of the glands around; a thick ceruminous discharge from the right ear; a temperature of 101° F.; the tongue strawberry coloured and pointed; and a pulse of 125. She appeared to be in a very drowsy condition but assured me that she had not taken any more veronal. Refusing absolutely to take any form of liquid medicine I ordered her sulphate of quinine tabloids, each containing two grains to be taken every three hours. This I did more as a "placebo" than anything else. The next day, the 22nd, the patient had periodical attacks of delirium alternating with periods of semi coma in which she lay on her back with her eyes half open. There was also a peculiar scarlatiniform rash over the face and arms; the bowels were obstinately confined. On the 23rd the patient was about the same. Fearing the symptoms might be due to some obscure brain lesion (due to the sun attack in Jersey) I called in further advice but could not obtain any decided opinion. On the 24th the patient was still about the same, the temperature ranging from normal to 101°. Constipation was obstinate even after two enemata and half an ounce of castor oil in capsule had been given. Having great suspicion that the patient was still taking veronal by means of trickery I again impressed the husband to redouble his efforts to find out whether this

was so. This he did by a very ingenious method of telling the nurse that my orders were for the patient to be moved into an adjoining room on account of the light and ventilation and whilst telling this he had full view of his wife by standing in front of a looking-glass and pretending to brush his hair. It was not long before he noticed the patient trying to get her hand beneath the mattress and on going immediately to the bedside he discovered that his wife had another bottle of veronal tablets concealed there. On each of the subsequent visits the patient implored me to give her some more of the drug, even going so far as to threaten if I did not comply with her wish. With the aid of a strong purgative and regular nourishment recovery was very speedy; all the symptoms disappeared except those of the skin which still remained in a rough condition. On the 29th she was able to leave London for the country. Before leaving she gave me the following information.

A few days before I first saw her, Dec. 13th, she had consulted a medical man on account of sleeplessness. He prescribed veronal in the form of the cachets, telling her to take one cachet containing eight grains just before retiring to bed. Instead of keeping to his directions on the evening of Dec. 10th she took two cachets (16 grains). Being dissatisfied with the result obtained she took 24 grains on each consecutive night. Immediately after this I saw her for the first time and found her suffering from the symptoms described in the beginning of this article. It was not until the 21st that she commenced taking the drug again, and during the time I was attending her until her secret was found out she took 128 grains. These were taken in the form of chocolates made up to contain eight grains of the drug in each sweet. I have inquired of several druggists who deal in this narcotic as to its composition but have failed to find one who can answer my question. Since attending this case I have met with three instances in which this drug has been employed. Two were of suicidal mania, whilst the third was a case of threatening delirium tremens. In all three cases the results were most satisfactory in every respect.

◆

FACIAL PALSY AS A FAMILY DISEASE.

By JOSEPH A. ARKWRIGHT, M.A., M.D. CANTAB.

INSTANCES of facial palsy occurring in two members of the same family are rarely recorded but are not unheard of. Several writers, moreover, have traced a general liability to nervous diseases amongst the near relatives of patients suffering from this paralysis. In 1887 E. Neumann[1] recorded the family histories of 37 cases of facial palsy and found in 24 at least of these cases the occurrence of pronounced nervous disease in near relatives. The commonest form in which the nervous taint appeared was insanity which occurred in ten of the families, convulsions or epilepsy appeared in seven, and chorea was present in seven; other nervous diseases occurring were general paralysis, ataxy, and paralysis agitans, besides in some of the families migraine, hysteria, and hemiplegia in addition to these. The frequency of chorea is interesting as a disease linking acute rheumatism and a nervous predisposition.

In five of the families facial palsy itself had occurred in other members and in one a case of convulsive facial tic. In one of these five families three sisters were attacked at 25, 25, and 19 years of age respectively, and in another (observed by Charcot) five cases of facial palsy occurred, three sisters, a child of one of them, and a grandchild; in the other three families a brother or a sister was affected besides the patient. As a further proof that predisposition takes a large share in causing facial palsy and that cold is not alone a sufficient cause, Neumann cites the occurrence of two or more attacks in the same individual and mentions six recorded cases in which facial palsy occurred more than once in the same patient, one patient having four attacks on alternate sides of the face and in four of the other patients both sides of the face being affected at intervals. Gowers[2] mentions eight cases of second attack. Nevertheless a hereditary predisposition to this particular neuritis sufficiently strong to cause four cases in the same generation of one family must be rare and seems worthy of record.

The first four of the patients whose cases are about to be described were members of a family of nailmakers in Worcestershire. The first one seen by me was a girl, 17 years of age, who noticed in the evening of August 17th, 1896, that her face was drawn to one side and that she could not close her right eye. I saw her on the same evening and found almost complete right facial palsy. She had pain in the right cheek and in the upper and lower jaws on the same side and in the right ear and there was some tenderness over the articulation of the lower jaw. The paralysis was very much less in two months and eventually disappeared altogether.

I was told by the above-mentioned patient that her elder sister when 16 years old had an attack of paralysis of the right side of the face from which she recovered in about six months.

A third sister came to me on Jan. 25th, 1899; she was 17 years old and she stated that on the previous day while she was at work making nails she felt a "snap" in the right side of her face and since then the right eye had watered. When I saw her the right side of the face was paralysed. She complained of not being able to distinguish the flavour of her food and of having a bad taste in her mouth. There was slight deafness of the right ear but she had never suffered from otorrhœa.

The fourth patient of this family was a man, aged 26 years, the brother of the three preceding patients and employed as driver of a steam-crane. On Feb. 10th, 1902, he noticed that his face was "drawn to the left." I saw him on Feb. 13th and found that he had right facial palsy which was not quite complete.

All these four patients lived together in the same house, and in the same road a few doors away there lived a first cousin of theirs whose wife and wife's mother were both under my care with facial palsy at different times. These two latter patients then though neighbours, were not blood relatives of the other four. The elder of the two, a married woman, 56 years old, was seen by me on August 22nd, 1902; she stated that on August 18th she had pains in her head and temples and on the 20th her face was noticed to have an unusual appearance. When I saw her there was right facial palsy; taste and hearing were not affected.

The other patient was a married daughter of the last-mentioned and was under my care some years ago on account of facial palsy from which she did not recover.

These cases confirm the conclusion of Neumann that although a cold draught may act as the exciting cause of facial palsy, still a very strong predisposition may be inborn. It is remarkable that two neighbouring families should have taken part in this series of cases but the distance of the cases in point of time makes it improbable that there was an infective agent which connected them.

Dover.

AN EARLY SYMPTOM OF ACHOLIA.

By HAROLD J. VAN PRAAGH, M.D. LOND.

A VERY early symptom of the interesting disease named by Dr. W. B. Cheadle acholia was observed in a case which I have had under observation for over 12 months. The patient, a female, two and a half years old, when I first saw her was very ill with symptoms of acholia—namely, loss of appetite, wasting, vomiting, and the typical porridge-like grey stool, composed chiefly of fatty matter. There was no jaundice or sign of other disease, such as tuberculosis. In spite of careful dieting and the use of mercury and arsenic she became steadily worse and seemed about to die from asthenia. However, she was sent away from her home in London to Margate, where she almost immediately made a rapid recovery, putting on flesh and eating her food quite well; at the same time the bile returned to the stools which resumed a normal appearance.

---

[1] E. Neumann: Archive de Neurologie, vol. xiv.

[2] Sir William Gowers: Diseases of the Nervous System.

Several attempts were made in the ensuing year to keep her well at home but they invariably failed. It was about this time pointed out to me by the child's father that some days before the stools commenced to lose colour an earlier symptom manifested itself—namely, coldness and dryness of the extremities. The child was carefully watched and on return [illegible] 'om, being rapidly [illegible] between blankets [illegible] and legs should be well covered up during the day, with the pleasing result that the threatened attack passed off and the child is able for the first time since her illness to live in London. The practical importance of observing this early symptom is obvious from the point of view of treatment. Whether it throws any light on the pathology of this obscure disease it is difficult to say. However, it does suggest that changes in atmospheric conditions may act as exciting causes of acholia in children predisposed to temporary loss of hepatic function. What these atmospheric changes are and how they act are problems that await solution.

It is with the object of calling attention to the fact that treatment of this early symptom may ward off the full development of acholia that I venture to bring the case before the readers of THE LANCET.

Welbeck street, W.

TOTAL EXTIRPATION OF THE PROSTATE FOR RADICAL CURE OF ENLARGEMENT OF THAT ORGAN.

BY J. WOOD COOKE, M.R.C.S. ENG., L.S.A.,
SENIOR SURGEON TO THE NORTH DEVON INFIRMARY.

A MAN, aged 71 years, was admitted into the North Devon Infirmary on Oct. 23rd, 1903, suffering from "retention of urine and false passage." For four years he had passed a catheter for himself many times daily, but of late he had done this with more and more difficulty and frequently with some hæmorrhage. On Oct. 23rd he was unable to micturate and sent for a medical man who passed a silver instrument, drawing off urine which was very blood-stained. The patient was then sent to the above institution. He had been losing flesh for some time and was in great pain. His bladder was much distended and a No. 9 silver catheter was passed and a large quantity of blood-stained urine was drawn off. No soft instrument would pass.

On Oct 24th I performed suprapubic cystotomy and left a long rubber tube (No. 12) in the bladder which was drained into a vessel containing phenol. The patient was much relieved and the urine became free from blood after a few days, but would not pass through a rubber catheter introduced into the bladder, although the bladder could be washed out through it. On Nov. 7th I decided to perform prostatectomy. I therefore opened up the suprapubic wound, snipped the mucous membrane with scissors over the most prominent part near the urethra, and enucleated the middle and right lobes of the prostate, assisted by pressure upwards in the rectum. I removed this portion with volsellum forceps after some trouble owing to its size and then enucleated the left lobe which was smaller, leaving the prostatic urethra intact. What was removed weighed altogether four and a half ounces; the bleeding was copious. I irrigated freely with hot saline solution and then replaced the rubber drainage tube as before. The patient was under A.C.E. mixture for about one hour, the enucleation taking about 20 minutes. On Nov. 11th he passed about two ounces of blood-stained urine naturally. On the 13th he twice passed a little urine and then for several days did not pass any. The drainage was continued and a No. 8 soft catheter was passed easily but no urine came through it. On the 17th a herpetic eruption appeared on the right side of the scrotum, the penis, the perineum, and the right gluteal region. The urine was still blood-stained and foul; the bladder was washed out daily. On the 23rd the drainage was stopped as the man passed urine quite naturally and has continued to do so up to the present date (Dec. 1st). The urine is acid in reaction and normal in character. It is passed with freedom and ease, the patient being up and about and practically quite well.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

SUNDERLAND INFIRMARY.

AN UNUSUAL SEQUENCE OF HERNIAL TROUBLES IN AN INFANT; OPERATIONS; RECOVERY.

(Under the care of Dr. STANLEY RAW.)

THE patient is at present aged ten months and was five weeks old when his mother took him to the infirmary complaining that she "had no peace with him" as he was continually crying and had great difficulty in passing urine. She had also noticed that there was sometimes a lump in the right groin and that when this lump was present he was more fretful than usual. On examining the child Dr. Raw found that he had a very long and tight prepuce and that the right external abdominal ring was abnormally large and easily admitted the tip of the little finger, though there was no hernial protrusion, despite the fact that the child cried incessantly during the manipulation. The mother having consented to have him circumcised the operation was performed on the next day and the baby was treated as an out-patient.

At the end [illegible] the difficulty of [illegible] ıted that the chil[illegible] had been frequently present. Hernia was now recognised and a light web truss was applied. On Oct. 16th the mother again took him to the infirmary and said that his bowels had not acted for more than three days, during which time he had vomited all she gave him, that the lump had been there all the time, and that he had cried almost incessantly. On making an examination a strangulated inguinal hernia was found and the mother, in answer to questions, said that she had not had time to look after his truss—her husband was a day labourer and they had a family of four—and as he was passing urine without any difficulty she thought that he was all right and only fretful. She further said that when she had time she gave the infant the breast, but on other occasions he "just had what was going" and that since the first operation his diet had consisted of breast-milk, bread, rice, meat, potatoes, and such like, each given indiscriminately and to suit the family convenience or to quell his crying.

Dr. Raw operated upon the case one hour after admission and on opening the sac fully two ounces of dark blood stained fluid escaped and a knuckle of intestine presented in the wound. The hernia was of the congenital variety. When the strangulation was relieved the intestine was deeply congested—almost black on its posterior aspect—whilst the marks of the neck of the sac were deeply indented on the gut. It was, however, returned within the abdomen and the sac was then freed. This was a matter of some difficulty owing to the intimate way in which structures of the cord were spread out and attached to it, and it was not possible entirely to free the cord at the neck of the sac, but it was eventually sufficiently cleared, after which it was divided transversely and the lower portion was sewn up in order to complete the tunica vaginalis. A pair of sinus forceps was then passed from without inwards through the abdominal wall above the internal ring down the inguinal canal and the upper part of the sac was drawn through the wall of the abdomen, where it was fixed, and a radical cure was completed by sewing the conjoined tendon to Poupart's ligament. The skin wound was united by interrupted sutures and an ordinary dressing was applied. On recovery from the anæsthetic the child was very restless and cried continually and was given seven grains each of chloral hydrate and bromide of potassium per rectum which acted admirably and he slept well all night. The bowels moved well the next day and he was given milk and barley water and eventually milk and made an uninterrupted recovery, the wound being soundly healed and the stitches removed on the seventh day. The patient left the hospital three days later.

On Dec. 11th the child was again taken to the infirmary with a history of the same symptoms but this time with a lump on the left side which had first been noticed on the previous day. Since his discharge from hospital his diet had been modified in accordance with the instructions given to his mother and she said that he had been much better and had not been nearly so fretful. The bowels had been quite regular until the lump appeared on the left side, since when he had had absolute constipation and he had vomited twice. On examining the abdomen it was found that the scar on the right side was perfectly sound and that there was no attempt at recurrence but the child now had a strangulated inguinal hernia on the left side. Dr Raw again operated upon him and found a state of affairs similar to the previous one, with the exception that the condition was not so bad as the strangulation had only existed for one day. The operation was completed as on the other side but on this occasion the parts were separated with comparative ease and no great difficulties were met with. The after-treatment was also similar and uneventful and the child left the infirmary on Dec. 22nd with the wound soundly healed.

The above sequence of catastrophes in one of such tender age must be very rare.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Researches on the Morphology of an Organism [illegible] with Carcinoma Mammæ and the Etiological Signif[illegible] of the Association.—On the Preparation of N[illegible] Agar.—A New Pathogenic Anaerobe found in P[illegible] Beef Infusion.—A Method of examining Water for [illegible] Presence of Bacillus Enteritidis Sporogenes.—Bac[illegible]logy of a Case of Emphysematous Gangrene.

A MEETING of this society was held on Jan. 19th, Dr. [illegible] KLEIN, the Vice-President, being in the chair.

Mr. K. W. MONSARRAT (Liverpool) read a paper o[illegible] Etiology of Carcinoma and Researches on the Morph[illegible] an Organism associated with Carcinoma Mammæ a[illegible] Etiological Significance of the Association. He sa[illegible] in 1899 he had read a paper in which he descri[illegible] morphological characters of an organism isolated [illegible] carcinomata. During the last four years he had cont[illegible] these researches. From a considerable proportion, 5[illegible] cent., of a series of specimens of carcinoma mammæ a[illegible] organism had been isolated possessing certain well-marked characteristics. By the study of this organism in culture and in animals experimentally inoculated it was shown that it possessed a double life cycle, the one a vegetative cycle in which reproduction took place by budding on culture media, the other a sporulating cycle and specially associated with the existence of the organism in the animal body. When inoculated into animals in the form of what had been called Type A it was capable of penetrating and inhabiting epithelial and endothelial cells and of initiating in these a process of proliferation. This process of proliferation was active and irregular and the new tissue thus formed infiltrated surrounding structures. In some cases it was associated with new tissue formation in neighbouring glands with a structure which bore a distinct resemblance to that of primary nodules. In one at least of the cases recorded nodules in viscera appeared not to arise from any local cell element and bore a close resemblance to the primary nodules. The organism could be demonstrated as an intracellular parasite in the endothelial and epithelial cells of the experimentally produced nodules. The same staining method showed the presence in carcinomata mammæ of bodies which appeared identical in character with the parasites in the experimental nodules and they were here found, as in the latter, both within and without the parenchyma cells.—Dr. W. S. LAZARUS-BARLOW said that he thought that the appearances described by Mr. Monsarrat were capable of another explanation and suggested that the organism found was due to contamination. The experiments showed proliferation of tissue produced as the result of injection of an organism of a low order of virulence. In the lymphatics themselves they produced a condition very like an endothelioma. He thought that the nodules produced were in reality granulomata.—Mr. S. G. SHATTOCK said that he did not think that the organisms found were the result of contamination but probably belonged to the order blastomyces. He suggested that the organism might be the cause of chronic mastitis rather than the cause of carcinoma. He asked Mr. Monserrat if he had examined the mamma in cases of chronic mastitis. He did not consider that the changes experimentally produced in the breast of a dog were typical of new growth but might be due to mastitis. The condition produced in the liver of the dog in which there was proliferation of the cells was a condition which required careful observation and he hoped that Mr. Monsarrat would be willing to submit his specimen to a committee of the society for further investigation.—Mr. MONSARRAT replied.

Dr. J. W. H. EYRE read a short note on the Preparation of Nutrose Agar.

Dr. KLEIN described the Bacillus Carnis, a new pathogenic anaerobe found in putrid beef infusion. It grew only under anaerobic conditions, a short, slender bacillus motile, and possessed of numerous flagella. It readily formed terminal spores oval to rod shaped and stained by Gram's method. It grew readily on serum, on agar, in gelatine, and in milk. Its colonies were translucent discs, at first rounded, later with raised margins with numerous knob-like projections. In gelatine in the depth it grew with numerous branched filaments; in stab gelatine culture the growth looked like mossy bundles. Neither blood serum nor gelatine was liquefied by the growth. Milk retained its fluid character. In glucosed media more or less gas was produced by the growth. Small doses of the bacilli or their spores were highly virulent to guinea pigs and mice, causing after subcutaneous injection extensive gelatinous infiltration and death in from 20 to 36 hours. The infiltration contained abundance of a clear sero-sanguineous fluid crowded with the bacilli. In the blood and the spleen [illegible] also present but less numerously. The peritoneum, the stomach [illegible] and the intestines were inflamed and often showed hæmorrhages. Occasi[illegible]onally the spleen and the liver contained infarcts. No gas was present either in the subcutaneous infiltration or in the inter[illegible]nal organs, nor did the subcutaneous exudation or the culture possess any odour.

Dr. R. T. HEWLETT read a note on a M[illegible] for the Presence of the Bacill[illegible]nteritidis Sporogenes. The method ordinarily ad[illegible] was to concentrate the micro organisms present [illegible] water by filtration [illegible] a Chamberland filter [illegible] organisms deposited [illegible] filter being then [illegible] suspended in a few c[illegible]bic centimetres [illegible] to 80° [illegible] and one cubic centimetre of [illegible] the suspension [illegible] each of several milk tubes which were heated [illegible] incubated anaerobically. Dr. He[illegible]wlett pointed [illegible] were several possible fallacies in this method [illegible] that it should be given up if possible. For the bacillus coli the use of concentrated [illegible] substituted but the concentration of milk [illegible]. It was found, however, that milk might [illegible] twice its volume of water and still [illegible] changes characteristic [illegible]. The method suggested was [illegible] least [illegible] tubes, each containing 40 cubic centimetres of milk [illegible] should be added 60 cubic centimetres of the water. After heating the tubes were incubated anaerobically at 37° C. in a Bulloch's apparatus or in a stoppered museum jar without a neck containing alkaline pyrogallol. By the use of a dozen such tubes 700 cubic centimetres of water could be examined in this way without the need for filtration.

Mr. L. S. DUDGEON and Mr. P. W. G. SARGENT contributed a paper on the Bacteriology of a case of Emphysematous Gangrene. The patient was a male, aged 24 years, under the care of Mr. G. H. Makins. He was admitted to hospital with a compound comminuted fracture of both legs sustained through a fall from a moving train. The right leg was amputated for simple traumatic gangrene as soon as the shock had passed off. The wound in the left leg had been cleansed and sutured. On the fifth day gangrene appeared in the left leg; the temperature was 103 2° F. and the pulse was 132. The skin was tense and pale and showed mottling due to dilated cutaneous venules. Emphysema was present round the wound and extended just above the knee. On removing the stitches there was an escape of brownish fluid and gas bubbles having a peculiar mousy smell. Ampu[illegible] was performed through the middle of the thigh. [illegible] muscles were œdematous and the subcutaneous showed greenish necrotic areas in places. Recovery was slow but otherwise uneventful. The urine contained neither sugar nor albumin throughout. Aerobic and anaerobic cultures were made from the emphysematous tissues. The staphylococcus albus was obtained in pure culture from the tissues immediately beyond that area. A bacillus which did not stain by Gram's method was obtained in both aerobic and anaerobic broth tubes in pure culture. The organism was a facultative anaerobe. In a large variety of media it behaved like the standard type of the bacillus coli. It failed to grow in its own filtrate, whilst most other examples of the bacillus coli group grew to some extent. It was pathogenic in guinea-pigs but did not produce emphysema even when inoculated together with the staphylococcus albus. It gave a feeble agglutination reaction with the patient's own serum. The staphylococcus isolated from this case showed no reaction with the same serum. Numerous examinations of the patient's blood were made, the chief point of interest being that there was a gradual transition from the small lymphocyte up to, and including, the myelocyte. Mr. Dudgeon and Mr. Sargent considered that the organism was a member of the bacillus coli family.

OBSTETRICAL SOCIETY OF LONDON.

Fibro myoma of the Uterus.—Pyometra in a Subseptate Uterus.—Abscess in the Wall of the Uterus.—Exhibition of Specimens.

A MEETING of this society was held on Jan. 6th, Dr. EDWARD MALINS, the President, being in the chair.

Dr. H. R. SPENCER read a paper on Fibro myoma of the Intra-abdominal Portion of the Round Ligament of the Uterus. He recorded a case of fibro-myoma of the intra-abdominal portion of the round ligament weighing six pounds, removed by abdominal myomectomy from a virgin, 24 years of age, who remained well after five years. He also gave a short account of the 13 cases previously published. A consideration of the facts furnished by these 14 cases showed that fibroids in this situation occurred usually in women over 40 years, Dr. Spencer's case being the youngest (24 years) and Winckel's the oldest (76 years). The tumours were more frequent on the right side than on the left (nine to five); in one case they were found in both ligaments and in another two tumours existed on one ligament. They might occur in virgins; they did not tend to prevent pregnancy or to cause abortion. They did not influence menstruation; menorrhagia and dysmenorrhœa were present, being due to uterine fibroids which were associated in half the cases. The tumours were subject to lymphangiectasis and to myxomatous and calcareous degeneration and might cause trouble after the menopause. They varied in size (from that of a nut to 12 kilogrammes) and might be pedunculated or sessile, intraperitoneal or subperitoneal. The pedicle might be the ligament itself, which was hypertrophied, o [illegible] tumour to [illegible] Special sy [illegible] abdominal pain and stiffness, pain on walking, sacral pains, intestinal pains, and pressure on the bladder had been met with. In Dr. Spencer's case the superficial abdominal reflex was much increased on the side of the tumour. Ascites was absent. The tumours, which varied in consistence, closely simulated ovarian, uterine, and broad ligament growths. The tumours should be removed as soon as they caused symptoms or attained a considerable size. The pedicle should be carefully tied and, when possible, the ends of the ligament should be united. If a sac were left after enucleation it should be closed by suture or drained. Two patients had died (of 11 operated on)—i.e., 18·18 per cent.—but the fatal cases had occurred 20 years ago.—Mr. ALBAN H. G. DORAN was not surprised to find that more than half of the cases were associated with fibroids in the uterus. In one instance where he had operated he enucleated a fibro-myomatous growth of the size of a pigeon's egg from the uterine end of one round ligament and removed the fibroid uterus. It was significant that, as in the case of fibroid of the broad ligament, the same kind of tumour was found both in the intra- and extra peritoneal portion of the round ligament with relative frequency in young subjects, one patient being only four years old. Fibroid disease was also relatively common in the band representing arrested development of a uterine cornu and in that case the corresponding round ligament was usually very large. Josephson and Falk believed that the rapid development of that ligament in fœtal life was the cause of malformation of the uterus. Hence fibroid of the round ligament might, in one sense, represent a teratological condition. Quite recently Mr. Doran had removed a uterus bicornis for a large fibroid developed in the septum—another half-teratological condition, not very rare. He dwelt on the surgical aspect of operations involving division of the round ligament. He thought that Dr. Spencer was right in recommending the union of the divided ends by suture when practicable. The outer stump should not be allowed to recede towards the internal abdominal ring.—Dr. W. SAMPSON HANDLEY said that he would like to hear Dr. Spencer's views on the pathology of these fibro-myomata of the round ligament. Mr. Doran had brought forward reasons for thinking that they might originate from persistent embryonic structures. He would suggest that possibly fibro-myoma of the broad and of the round ligaments was genetically identical and that both varieties of growth might originate from accessory Fallopian tubes. Kossmann had shown how frequently these accessory tubes were present and it was now known that certain cysts of the broad ligament arose from them. He had himself proved the presence of plicæ in such cysts. Since fibro-myoma was known occasionally to arise from the muscle of the normal Fallopian tube it seemed probable that accessory tubes might give rise not only to cysts of the broad ligament but to fibro-myoma of the broad and round ligaments.—Dr. SPENCER, in reply, said that he had been particularly interested in the remarks of Mr. Doran who had done so much valuable work on fibroids of the uterus and broad ligaments. He thought that there was much to be said for the teratological origin of these tumours, especially as they sometimes contained adenomatous tissue as in Cullen and Bluhm's cases. The enlargement of the round ligament in unicornuate uteri, mentioned by Mr. Doran, he had not previously been aware of. With regard to Dr. Handley's suggestion, it had not been proved to his (Dr. Spencer's) satisfaction that accessory Fallopian tubes existed, and when it had been proved he could see no reason why they should be brought in to explain a simple fibro-myoma occurring in a fibro myomatous structure like the round ligament.

Dr. W. F. VICTOR BONNEY read a short communication on a case of Pyometra in one-half of a subseptate uterus. Apart from the rarity of such a condition the case presented a remarkable resemblance to a pregnancy occurring in a uterus the seat of extensive perimetric adhesions. The patient had a history of recurring attacks of acute peritonitis extending over a period of many months. She had had a child seven months previously to the onset of the symptoms. There had been amenorrhœa for the two months immediately preceding the operation and the uterus was enlarged to a corresponding size and appeared to be imbedded in an inflammatory mass. There was copious secretion in the breasts. Opportunity for impregnation had occurred at about the requisite period and had been shortly succeeded by a recrudescence of the inflammatory symptoms. On opening the abdomen the uterus was found to be the seat of universal adhesions and to be enlarged in accordance with the pre-operative diagnosis. The upper part of the uterus was cleared of adhesions with difficulty and the tubes were inspected and found to be unthickened and normal, though adherent. Dr. Bonney, believing that the patient was pregnant in a universally adherent uterus, determined to incise the fundus and to remove the gestation sac. Her condition, which was grave, was held to be the result of the increasing enlargement of the pregnant uterus dragging upon the extensive adhesions to the intestines. On incising the uterus a quantity of pus escaped from a cavity which, on further exploration, was held to be the left half of a subseptate uterus, the median septum having become adherent to the left uterine wall about the level of the internal os. The uterine sac was stitched to the abdominal wound and drained and the patient made a good recovery.

Dr. ARNOLD W. W. LEA related a case of Abscess in the Wall of the Uterus, in a patier [illegible] at the time of delivery, [illegible] puerperium and ruptured in [illegible] patient had suffered during the second week after delivery from severe recurrent pain in the hypogastrium but was able to walk about. Six weeks after delivery she was suddenly seized with intense abdominal pain, followed by symptoms of not at 70, as erroneously stated in the report. During a few weeks Dr. Baker curiously enough came upon four other cases of trypanosoma in the blood, thus showing that the typanosoma was not so rare as one might have expected. The patients with the trypanosoma in their blood came to the dispensary because they had an attack of fever and there was very little else the matter with them. They were under observation during the whole time at Entebbe. He himself saw all the men two months ago before he came away and they were all practically well. Every one of them had been punctured several times and there were no ill effects from it. They got up from the chloroform and after 20 minutes they went away. They had large numbers of trypanosomata in their blood, but later large quantities of blood had to be taken from them before the trypanosoma could be found. In no case did they show the trypanosoma in the cerebro-spinal fluid in the early months, but later (in July) two of them showed the trypanosoma present in the cerebro-spinal fluid. Consequently the theory suggested itself that the trypanosoma was possibly the cause of sleeping sickness and therefore they looked very carefully for any signs of sleeping sickness in those patients. Nothing, however, was found to be the matter with them or the others. They were again examined a month afterwards and no trypanosomata were found. He also examined at the same time the patient who had the trypanosoma in his cerebro-spinal fluid and found none present. He thought that possibly in these two cases the trypanosoma found in the cerebro-spinal fluid was due to an appreciable amount of blood having got into the fluid. That, he knew, was a general objection to their theory though it did not apply to a large number of cases. But those two cases were still under observation at Entebbe and he thought that they might still contract sleeping sickness. After Dr. Castellani left, the subject being a very suggestive one, they naturally devoted their attention practically exclusively to the trypanosoma. The commission carried out several post mortem examinations and looked for the streptococcus and found it in several cases but not in all. They found the diplococcus pneumoniæ in two cases. Then they performed a large number of lumbar punctures in cases of sleeping sickness and in practically every case—he could not say the exact number of cases—they found the trypanosoma in the fluid. Sometimes the trypanosomata were extremely scanty. In some cases they had to repeat the puncture two or three times before finding the trypanosoma but eventually it was always found. In some of the cases there was a large number of trypanosomata. He was perfectly sure the trypanosoma did not get into the lumbar fluid owing to leakage of blood. A few days before he left Africa he examined the cerebro-spinal fluid of a native and found it teeming with trypanosomata and there was not a single red corpuscle in 20 fields of the microscope. That question of the trypanosoma in the cerebro-spinal fluid in sleeping sickness applied not only to Uganda but Dr. C. A. Wiggins had examined a large number of sleeping sickness cases on the north east of Lake Victoria Nyanza and he found the trypanosoma in every case in the cerebro-spinal fluid. He (Dr. Nabarro) examined the cerebro-spinal fluid of a Persian suffering from sleeping sickness and he found it teeming with trypanosomata. In cases where a large amount of the fluid was present it was sometimes difficult to find the trypanosoma but on repetition of the puncture the trypanosoma was generally found. Sometimes in a lumbar puncture the fluid came out at the rate of one drop in half a minute and the flow had to be increased by aspiration and in that way a good deal of time was saved and it did not do any harm to the patient. The next question was that of lumbar puncture in cases of "controls," cases which did not show any obvious sign of sleeping sickness. It was rather difficult to get a native to come to take chloroform and to have a puncture performed upon him. He believed 15 of those cases were operated upon in the laboratory at Entebbe and all with a negative result. Dr. Wiggins had examined seven "control" cases, all with a negative result. And then there were those five patients whose cases he had mentioned, which it was very important to bear in mind because they had a considerable number of trypanosomata in their blood, and, moreover, on several occasions there was an appreciable deposit of blood in the cerebro-spinal fluid, but on examining them later the trypanosoma was not found in the cerebro-spinal fluid. Out of 16 cases of sleeping sickness the trypanosoma was found in the blood of 15. In the sixteenth case it could not be found. He classified those cases into different categories. The first was the examination of the blood of healthy people in non-infected areas in Uganda. There were parts of Uganda, especially the interior, where there was no sleeping sickness. People came from there into Entebbe to do a month's work as labourers and ten of them used to be sent every day to have their blood examined. From that non-infected area 66 people in all had their blood examined and all with a negative result. That was a very interesting and important fact which ought to be borne in mind. Similarly from a non-infected area in East Africa quite away from Uganda 50 natives were examined and in every case with a negative result; therefore in 116 observations in healthy individuals from non-infected areas the trypanosoma was absent from the blood. He believed he could say without error that all, perhaps excepting one, of those were examined by the centrifuge. That was to say, ten cubic centimetres were drawn off and the fluid was centrifuged and the serum was pipetted off, then the fluid was centrifuged again and the serum was pipetted off, and then it was centrifuged again and the serum was pipetted off; then the residue was examined. The fluid was re-centrifuged after an interval of ten minutes. The next category included natives from the infected areas—the shores of Victoria Nyanza and the islands especially. In the blood of 74 patients examined from those districts the trypanosoma was present in 17 cases, or 23 per cent. These numbers they would find slightly different from those given in the report of the Royal Society. They excluded other cases which did not come quite into this category. Lastly, there were the five cases of natives and one European who lived in Entebbe who developed the trypanosoma. From these data naturally they began to think that the trypanosoma had something to do with the disease and they accordingly turned their attention to the tsetse fly. They inquired in Entebbe whether they had the tsetse fly there and they were told "No." Afterwards at the end of March or the beginning of April they went out into the forest and found the fly. That showed then that they could not rely much on what they were told by the natives in Entebbe. But the fly was found and it was brought in by hundreds every day. He might perhaps say a few words about the distribution of the fly in Uganda. Very soon after finding the fly in Entebbe they thought it would be interesting to ascertain if possible whether the fly was found throughout Uganda and a circular letter was sent to all the missionaries and others to ask the natives to collect flies and to send them in. A large number of flies were sent in and a map was published by the Royal Society showing the distribution of the fly throughout Uganda. It was interesting to note that in one part of Uganda—on the right bank of the Nile—the fly went a long way inland along the course of the Nile. Why that was so they had not been able to make out. On the left bank of the Nile in the Uganda province the fly was practically never found in the interior. He asked for flies to be sent from the left bank of the Nile. This had been done, but hitherto not one tsetse fly was received. If they looked at the map showing the distribution of the tsetse fly and sleeping sickness they would find a very close similitude between them; that practically the distribution of the fly and of the disease was identical. He thought that was a very strong point in favour of the fly being the cause of the dissemination of the disease. He had travelled up the country and was struck by the fact that the fly was extremely localised to forest areas and to the water's edge and to dense undergrowth. He never found it on the papyrus swamps or the grassy plains. The islands were hotbeds of the disease and some islands were practically depopulated. He would like to say a few words as to the experiments they performed on animals. They used a large number of animals—monkeys, dogs, guinea pigs, sheep, goats, rats, donkeys, oxen, and a jackal, and yet unfortunately the animal experiments were not very satisfactory. Only monkeys, dogs, rats, and the jackal were found susceptible to the trypanosoma. The other animals injected failed to show the trypanosoma in their blood. In the case of the monkeys, very curiously a few weeks after inoculation trypanosomata appeared in the blood, and in some cases became quite numerous, but after a short time—perhaps a month—they began to disappear and when he left Africa practically all the monkeys failed to show trypanosomata in their blood and were nearly all in a perfect state of health. One of the monkeys died from tuberculosis and three others also died, but whether from sleeping sickness or not it was difficult to say. One point in this connexion that he would like to bring out was that they did parallel experiments. They injected animals in pairs, one with the blood trypanosoma and the other with the cerebro-spinal fluid trypanosoma. The injections gave rise to a similar appearance in the monkeys and also in the dogs and other animals, and if the trypanosoma did not appear in the one it did not appear in the other. That led them to think that they were dealing with one and the same trypanosoma. Other experiments they carried out seemed to favour that view. For instance, after the trypanosoma had disappeared from the blood in the injected monkeys he reinjected them with the same trypanosoma to see whether the trypanosoma would appear again in the blood, but it did not as the animal had apparently become to a certain extent immune. He then injected the other trypanosoma (from blood or cerebro-spinal fluid, as the case might be) and when he left the country the trypanosoma had not yet reappeared in the blood of monkeys thus reinjected. That, he thought, would serve to show that the two trypanosomata were identical. He came next to the feeding experiments which had given rise to a certain amount of criticism. The flies which they used were similar, with very few exceptions having all been [illegible] and they were always kept over [illegible] a good appetite. On the next [illegible] animal specially kept for the purpose which was called a "fresh fly" monkey or dog, as the case might be, with a clean bill of health. Then the flies were kept for 24 or 48 hours and finally put into the feeding box for the particular experiment to be carried out. The rearing of flies was very protracted, as each female had just one larva and it took six weeks to hatch and to become a fly. On the whole about 120 young flies were developed during the nine months in Entebbe. Dr. Sambon, in his paper, stated that fresh flies when put on a monkey took only two or three weeks to give rise to trypanosoma infection, whereas those first fed on sleeping sickness patients took six or eight weeks. That was quite true, but he thought he could give two or three reasons why that was the case. The fresh fly experiments were rapidly performed. In other words, having got perhaps 150 flies a day these were kept over night and then put on a monkey so as to get a positive result as soon as possible. Being always hungry the flies naturally fed very well and he thought that explained why the experiment succeeded Then as to the six or eight weeks which were taken by the flies fed on sleeping sickness patients to give rise to trypanosoma infection some of the patients did not like the flies and frequently they put their hands under the blankets and took off the cages containing the flies so that quite few flies were fed. It seemed, too, that the flies got rather tired of the same patient and if kept on one patient they did not feed nearly so well. But what Dr. Sambon had said about finding trypanosomata in other animals was a good sound suggestion, and they did find trypanosomata in other animals. He had not yet presented his report to the Royal Society but he did find trypanosomata in other animals, only they were different trypanosomata. As to the question of trypanosoma in the monkeys, he could say emphatically that he never found the trypanosoma in a healthy monkey straight from the fields, so that he was quite sure the trypanosoma was not a normal parasite in the monkeys in Entebbe. In his subsequent remarks Dr. Nabarro said he thought that the death of Sir Patrick Manson's patient gave support to the theory that sleeping sickness was caused by the trypanosoma.

Dr. F. W. MOTT said that his experience was pathological, not epidemiological. At present there were two theories for the epidemiology: (1) trypanosoma, (2) diplococcus; and Dr. Castellani had latterly adopted both the micro organisms being [illegible] the [illegible] had [illegible] was [illegible] Exa[illegible] Eur[illegible] correctness of his presumption that the chronic inflammation of the membranes and nervous substance of the whole brain and spinal cord existed as exhibited by an extraordinary accumulation of lymphocytes in the subarachnoid space and in all the rivers, rivulets, and streams of the cerebro-spinal fluid which surround the blood-vessels (the so-called perivascular lymphatics)—channels which carry the special nutrifying fluid of the brain and serve not only for the special metabolic processes of nutrition and the gaseous exchanges, but also to wash out the waste products. Such accumulation of lymphocytes would interfere mechanically with the circulation of the fluid, and biochemically by the lymphocytes taking up the oxygen which was normally intended for the nervous structures; hence a condition would arise not unlike that which he had seen in internal hydrocephalus, where ventricular accumulation of fluid produced lethargy and stupor, paresis, tremor, fits, &c. At first there was functional depression rather than destruction of the cells and fibres, later a true degeneration occurred. He might say that he had observed in several cases which he had examined, including the European case, a chemical change in the myelin sheaths without actual Wallerian degeneration, and he had observed the same appearance in certain chronic infectious processes. In the two cases which were in Charing Cross Hospital a striking feature was the universally enlarged lymphatic glands and he found on looking through Colonel Bruce's report that in every case, with one exception, the glands were enlarged—the exception being a case of cerebral tumour and not sleeping sickness. A missionary who attended the meeting of the Pathological Society four years ago stated that enlarged glands constituted a well-recognised symptom. They had then three definite pathological facts: (1) excess of lymphocytes in the blood contained in the vessels of the brain; (2) accumulation of lymphocytes in the perivascular lymphatics and the subarachnoid space; and (3) enlarged lymphatic glands. In two of the cases recorded by Colonel Bruce the glands were suppurating. Admitting that the glands of the groin and other superficial glands were very liable to enlargement in the negro, owing to sores, &c., and admitting that syphilis was very prevalent among negroes, still the fact remained that those causes would not account for practically nearly all cases having glandular enlargement or for [illegible] what constituted the [illegible] the nervous system. W[illegible] parasite being really a blood parasite—or was it due to an organism such as [illegible] which as far as [illegible] had discovered [illegible] is faith as the cau[illegible] he subsequently held (after his observation of the trypanosoma in the cerebro spinal fluid), act as an important subsidiary cause in a secondary infectious process? He stated in his report to the Royal Society that he had grown it with absolute certainty (and always pure) from eight out of ten post mortem examinations from the cerebro-spinal fluid and blood of the heart taken with aseptic precautions. *In vita* he (Dr. Castellani) had found it only once in the blood, but he had grown it in two cases out of three from the cerebro-spinal fluid removed by lumbar puncture. In the *Journal of Tropical Medicine* of June 1st, 1903, he had given further observations showing that that organism was present in the blood of the heart in 32 out of 39, and in 30 out of 39 in the cerebro-spinal fluid. In connexion with those observations Dr. Mott remarked that that infection would account for the lymphatic gland enlargement and for the appearances which the cerebro-spinal subarachnoid and canalicular systems manifested in every genuine case of sleeping sickness. He had only had the opportunity of examining the lymphatic glands in two cases; one was that of the European patient of Sir Patrick Manson and the other was an enlarged gland which he had not previously examined from one of his old cases. In both of them he found the diplococcus. In the case of the former every section of the gland showed numerous clumps of those organisms lying in the lymph channels of the gland, which were filled with cells and fibrin like the appearances presented by the alveoli in croupous pneumonia. It might be said that diplococcus or streptococcus infection was due to bed-sores and lung disease. He did not think so, for the following reason. Dr. Eyre and himself had withdrawn cerebro spinal fluid *post mortem* from 21 cases of insane patients who had died mostly with lung disease, and many with bed-sores; and after careful examination in not one did Dr. Eyre find diplococci, and in one only streptococci, and that was a case of suppurative parotitis. Staphylococcus aureus and albus were occasionally found and sometimes bacillus coli. He had been unable to find trypanosoma in the blood-vessels or subarachnoid spaces of sections of the central nervous system. [illegible] It might be [illegible] nly in smears, [illegible] himself had found that sections of the brain of a rabbit dying from Surra showed enormous numbers of the trypanosoma, enough to produce mechanically the profound changes observed in the nervous system. But against the fact that they could not be seen in the vessels it might be said that they took on a different form or were hidden in the tissues in sleeping sickness. He did not regard the experiments on animals as conclusive. The strong arguments in favour of the trypanosoma being the cause of that remarkable disease to his mind was the admirable research as regarded the distribution of the fly, the distribution of the disease and its correlation with the existence of the fly and the existence of the trypanosoma in the blood of the natives by Colonel Bruce and his assistants. The case under Sir Patrick Manson's care was of great importance in showing the chronic nature of the disease. That was of exceptional interest because they found that the patient for a long time exhibited the trypanosoma in the blood and then died with the diplococcal infection which in this instance might therefore be assumed to be related to the onset of the symptoms.

Dr. C. F. **HARFORD** said that he had no right to say anything on the subject of sleeping sickness because he had not had an opportunity of making recent observations with regard to the disease. He had, however, a case of sleeping sickness under observation about 14 years ago and his attention was drawn to it by the natives who seemed to have a close acquaintance with the disease, although in their part of Africa (the Upper Niger) the disease presented itself in a sporadic form. One point which seemed to impress itself upon the intelligent natives was the occurrence of enlarged lymphatic glands and they had the idea that if the lymphatic glands were removed the disease would be cured. They told him that they had performed operations of that nature. He thought that they probably regarded all cases of enlarged lymphatic glands as cases of sleeping sickness and removed enlarged glands in cases where sleeping sickness had not developed and thus thought that they had cured the disease. He made inquiries of educated natives who knew a good deal about the subject and one fact they drew attention to was that no negroes in other parts of the world, as in the West Indies, and no American negroes seemed to develop the disease. Dr. Harford proceeded to say that he was specially interested in the subject from a practical point of view. There had been in his college, the Livingstone College, student missionaries who had had a good deal to do with the disease, who had been in the worst districts of the Congo and had seen much sleeping sickness there. He was also connected with the Church Missionary Society, and being physician to that society he had much to do with missionaries who had come from districts where the disease existed. Dr. A. R. Cook and Dr. J. H. Cook, he was sure, had contributed something to the elucidation of the problem of the cause of the disease. He did not know abler men than those two brothers, although they had not had much opportunity for scientific research, being arduous medical missionaries. He thought they were greatly indebted to Dr. Sambon for having brought before them such a carefully prepared paper containing a large amount of evidence with regard to the important disease which they were considering and he hoped they might express the desire that some practical step should be taken to deal with the disease. It seemed to him that whatever might be the final conclusion on the subject there could not be the least question that the tsetse fly was a terrible scourge, not only to man but to animals, and that every effort should be made to see what might be done to deal with the fly. He might mention that one practical step had been taken in Uganda by the authorities of the Uganda Industrial Mission who, fully realising the danger of having their establishment in a district where the tsetse fly was prevalent, had actually taken steps to abandon most desirable premises in order to get away from that district. He thought that certainly they as a society ought to make practical use of the very important discovery in connexion with the cause of sleeping sickness.

Mr. **JAMES CANTLIE** asked if the disease was limited to the areas represented on the map. They were all afraid that it would spread on the Nile. He wished to know whether it was stationary or steady in its progress.

Dr. H. T. **BULSTRODE** remarked that so far as he understood the disease its medium of conveyence was the glossina palpalis and if this view was wholly true the danger of contracting the disease must be limited to the areas already inhabited by the fly or areas to which it may be carried. They had heard about the distribution of the fly in Uganda but not in Senegambia or Angola. He would like to know whether the areas of the disease and of the fly corresponded there. In his paper Dr. Sambon drew a terrible picture of the possible spread of the disease up the Nile across the Suez Canal and along the coast to India. He (Dr. Bulstrode) failed to see how that could happen. So far as he could gather, the disease was not directly communicable from person to person but only through glossina palpalis and therefore in the area of distribution of that fly. Dr. Nabarro had spoken of the depopulation of an island by sleeping sickness. This fact suggested that the distribution of the fly had extended or that the trypanosoma might have other agencies of spread than glossina palpalis. Otherwise it was difficult to understand how the island in question became peopled in the first instance. Dr. Bulstrode thought that if the distribution of glossina palpalis was not altering there should be little danger to the residents of fly-free areas in the importation of infected human beings, as the disease was not directly communicable. Probably, however, they were only in possession of part of the whole story.

Dr. **NABARRO** remarked, in reply to Mr. Cantlie, that the disease was spreading along both shores of the lake and in each case it was approaching German territory. The Germans were becoming rather anxious about it and sent one of their colonial surgeons over to Entebbe to study the disease there along with themselves. They showed him the fly and told him different facts concerning it and he returned ready to deal with the disease if it should reach his territory. With regard to how the disease was spread, that, he must own, was a difficult question, because the trypanosoma was very scanty in the blood of patients, but possibly more numerous in the earlier than in the later stages of the disease. Then, too, the latent period might last for several years, so that the patients might have had the infection imparted to them years before the disease showed itself. He took it that the fly had been in the country for a long time, but that the trypanosoma had only recently been introduced into the country. He knew for a fact that around the Albert Nyanza, to the north-west of the Victoria Nyanza, the fly was found all along the shore and yet there was no sleeping sickness there. That had been discovered shortly before he came away. One feared that if infected patients got there they might spread the disease because the fly was there. On the other hand, when infected patients got into the interior of Uganda the disease died out with them because the fly was not found there, just as malaria would where there were no mosquitoes. It was quite possible that certain animals might harbour some trypanosomata but these seemed to be different from the trypanosomata found in cases of sleeping sickness. No fewer than 50,000 people died last year from sleeping sickness on the shores of the lake and in Usoga, so that the disease was a serious thing from an economic point of view.

Sir **PATRICK MANSON** said there was no doubt about the existence of sporadic cases as mentioned by Dr. Harford. Occasionally, cases had occurred on the West Coast of Africa, as, for instances, in Senegambia, Sierra Leone, and the Upper Niger, and there the disease did not appear in an epidemic form. It would be interesting to know the relation that these cases bore to the presence of the trypanosoma in the general population of those particular places. A good many years ago he was asked to see a patient who had come from German East Africa and who presented a combination of symptoms that he confessed he could not understand—a peculiar tachycardia, a peculiar irregular temperature, an enlarged spleen, great prostration, and half a dozen other symptoms which now he knew must have belonged to trypanosomiasis, possibly to sleeping sickness. If there was one case of that disease in German East Africa why should there not be many cases? It was quite possible that the disease might prevail in many places but had not been recognised. This was borne out by something that had been ascertained during the last few weeks as regarded another disease which belonged to the same category as trypanosomiasis. He alluded to a disease known in India as kala-azar, which was probably due to a parasite inhabiting the spleen and the liver. Formerly it was thought that this disease was limited to certain areas in India and had travelled in epidemic form and depopulated the places over which it passed. But now it appeared that a similar disease existed in China and only lately a German had recorded a case of that disease in an individual who came from Peking. In some places the disease was epidemic and in others it was sporadic. It would be exceedingly interesting to find out what were the exact conditions which determined endemicity and sporadicity. It had been suggested that the entrance of the trypanosoma into the cerebro-spinal fluid was the determining cause of the symptoms of sleeping sickness. He thought that view was a little far-fetched. He thought that the trypanosoma was the cause of sleeping sickness but to particularise as to the precise way in which it caused sleeping sickness—by its entrance into the cerebro spinal fluid for example—was going a little beyond the facts. When a patient was afflicted with encephalitis or inflammation of the cerebro-spinal system naturally the parts were all congested and the vessels were so distended that there was an escape of blood undoubtedly at times into the cerebro-spinal fluid and they [illegible] like the trypanosoma [illegible] against phagocytes a [illegible] present in the fluid for a considerable time. An analogous condition was seen sometimes as the result of filaria of the blood giving rise to stasis regurgitation in the lymphatic vessels; if the tunica vaginalis was involved in such a case there were sometimes rupture and the effusion of lymph into the cavity of the tunica vaginalis. If this lymph were *examined there would be found in it millions of living* filariæ, these being much more abundant than in the ordinary lymph. The reason of this phenomenal abundance of filariæ was that the filariæ escaped into the cavity of the tunica vaginalis but could not find their way out of the serous sac and so accumulated there. The same thing happened in the case of the escape of trypanosomata into the cerebro-spinal fluid, and therefore he thought that they should not attach too much importance to the notion about the appearance of the trypanosoma in that fluid in connexion with the pathology of the disease. He would like to say one word in conclusion. He thought that the profession had been a little unjust. He did not want to speak about *questions of priority, but he thought that the profession* had been a little unjust in the way in which it ignored the work of the early investigators into the Uganda disease. When Dr. Low, Dr. Castellani, and Dr. Christy were sent out by the Royal Society they had specific directions to investigate on certain lines. More especially they [illegible] was the cause [illegible] if the areas of [illegible] or not. That piece of work they carried out thoroughly and they got little credit for it. A second thing they were to do was to endeavour to find out any micro-organism that might possibly be the cause of the disease. That they certainly did. In the first place, *they determined the presence of the diplococcus* which Dr. F. W. Mott said he had also found in some of the cases that he had investigated and they further demonstrated the presence in a large proportion of cases of the trypanosoma in the blood. He thought that those early commissioners sent out by the Royal Society had done their work thoroughly and ought to receive due credit.

Dr. MOTT said that he had only found diplococcus in every section of the glands and other organs in Sir Patrick Manson's case. He was referring to Dr. Castellani's work when he said 80 per cent.

Colonel T. C. MCCULLOCH, R.A.M.C., said he believed that Colonel Bruce had examined a number of flies and actually found the trypanosoma in their proboscides. He would also like to point out an inaccuracy perhaps in Dr. Sambon's paper. When Dr. Sambon spoke of the conveying of malaria by malarial-infected blood he could scarcely mean malarial-infected blood.

The PRESIDENT said that the cordial thanks of the society were due to Dr. Sambon for his paper which had led to a most instructive and valuable discussion.

Dr. SAMBON, before replying to the various criticisms, said that he must in the first place thank those present very much for the kind way in which they had listened to him. He was very pleased to hear Dr. Nabarro's remarks. Dr. Nabarro had explained the short period elapsing between the first bite and the appearance of the trypanosoma in "fresh-fly" monkeys by the fact that those experiments were pushed and that many flies were used. But from the "Further Report" he gathered that in the other sets of experiments equal numbers of flies were used. He thought it was to be regretted that Dr. Nabarro and his collaborators did not try experiments with stomoxys which by some observers was said to convey nagana. It was also to be regretted—knowing that the fly was to be found on one bank of the Nile and not on the other—that they did not thoroughly investigate this all-important point. Dr. Nabarro had further remarked that the rearing of flies for experiments would involve years. Well, perhaps the results would have been obtained later, but they would have been of a more definite and valuable kind. Dr. Bulstrode had asked if the areas of the disease and of the fly corresponded in Senegambia and Angola. As to Senegambia and Angola we had no information, but on the Congo Dr. Brumpt, from very careful investigations, had shown that there was a very close connexion between the fly and sleeping sickness. There were cases in which Dr. Brumpt noticed that the disease was more prevalent amongst women and in other places amongst men. He was able to show that where the women got water from certain places they contracted the disease but not so with the men who remained inland for agricultural work. In other cases where the men went to fish they contracted the disease but the women who [illegible] in their villages did not do so. Dr. Sambon agreed [illegible] it could be conveyed by means of needle infection with malarial blood. For instance, at the St. Spirito Hospital in Rome *Dr. Panichi* was examining a *slide of malarial blood* and broke the slide and cut his finger and after a short time of incubation he suffered from a severe attack of malarial fever. In the discussion that followed my paper at the last meeting Professor Lankester said I should correct the statement in my paper with reference to the importance given by Dr. Castellani to his own discovery. I am sorry that I cannot oblige Professor Lankester. I am well aware that Professor Lankester contends that Dr. Castellani did not understand that the trypanosomes which he had found in the cerebro-spinal fluid of sleeping sickness cases could have anything to do with the disease until Colonel Bruce pointed it out to him. I know also that numerous articles have appeared in medical and non-medical papers expanding greatly on Dr. Castellani's discovery of a streptococcus in sleeping sickness and even going the length of reproducing a factitious illustration of the bacterium. But all this is very unjust. I used the very words employed by Colonel Bruce in his progress report:—

> Dr. Castellani informed us of the work he had done, one especially interesting observation being th [illegible] the cerebro spinal *fluid* in five o [illegible] Castellani remained in Entebbe [illegible]

In his further report Colonel Bruce says:—

> At the time of the arrival of the commission Castellani did not consider that this trypanosoma had any causal relationship to the disease but thought that it was an accidental concomitant like filaria perstans.

Now let us place ourselves for a moment in Dr. Castellani's place when he found a trypanosoma in the cerebro-spinal fluid of a patient suffering from sleeping sickness. Should we have jumped at once to the conclusion that the trypanosoma was the cause? Later, when Dr. Castellani found the trypanosoma in five out of 15 cases, would it have been reasonable to incriminate the trypanosoma when it was known that trypanosoma fever was present in Uganda? But when the trypanosoma was found in 70 per cent. of sleeping sickness cases and not in the cerebro-spinal fluid of trypanosoma fever cases and never in healthy persons, was it necessary for anyone to point out that there might be a connexion between the trypanosoma and sleeping sickness? Professor Lankester disparages my remarks concerning the transmission of sleeping sickness. He says that there is nothing in them. The suggestion that *glossina palpalis* was the carrier would occur to anybody. The real interest in the matter is that Colonel Bruce found the glossina palpalis where it was not previously known. I have fully explained in my paper the reasons which led me to incriminate a West African tsetse, and more especially the widely distributed glossina palpalis. I know full well that the suggestion of a tsetse fly occurred to many; it *occurred to Professor* Blanchard, to Professor Laveran, to Dr. Mesnil, to Dr. Castellani, to Dr. Brumpt, to Colonel Bruce, to Professor Lankester, and to *many* others, but, as Dr. Brumpt stated in the discussion, there is some difference between a mere suggestion based on analogy and the deduction from carefully observed facts. As to the discovery of the tsetse in Uganda, which had been removed on account of a tumour which he believed to be a secondary deposit resulting from carcinoma of the mamma. The tumour of the mamma had been removed four years ago. It recurred and on account of this double oöphorectomy was performed and treatment by the x rays was afterwards used. Secondary tumour in the eyeball was an extremely rare condition and the specimen had not yet been examined microscopically, so that its nature was still uncertain.—Mr. Henry Rutherfurd showed a specimen of Unilateral Hydronephrosis due to kinking of the ureter by the renal vessels. He also showed a Humerus the seat of rapidly developing sarcoma having a relation to an injury. Three weeks after a fall the patient was examined but no evidence of fracture was found. Three days later fracture resulted from another fall and a tumour then formed very soon. The arm was amputated seven weeks after the first injury; the patient, who was a boy about six years old, died from shock.

ROYAL MEDICAL SOCIETY OF EDINBURGH.—A meeting of this society was held on Jan. 8th, Dr. H. D Shepherd being in the chair.—Mr. J. W. Dowden gave an address on the Treatment of Shock. After discussing the varieties and etiology of shock he referred to an interesting series of experiments made in America on the effect produced on vaso-motor pressure by laceration of various parts of the body in animals. In almost all regions the effect of injury was increase in blood pressure, the abdomen and the scrotum being exceptions. In preventing shock as the result of anæsthesia Mr. Dowden believed that there were great possibilities in the use of local anæsthetics. Such major operations as the removal of an arm with the corresponding part of the shoulder girdle had been performed under cocaine, the patient being quite ignorant of what was going on. In the use of general anæsthetics the preparation of the patient as ordinarily done by a process of starvation and purging should not be too rigorously carried out Even within an hour or two of the operation readily absorbed food might be given by the mouth and the patient might have a nutrient enema. In the actual treatment of shock warmth and friction were important factors. Of drugs strychnine and digitalin were the most valuable. Any good effect of alcohol was probably temporary and due to its action as an irritant, such an irritant as capsicum being even more effective. Injection intravenously of normal saline solution, except in cases of hæmorrhage, was more dangerous than useful.—A paper on Pubiotomy by Dr. F. D Simpson was read in his absence by Mr. A. MacRae.—Dr. T. B. Hamilton read a paper on Pleural Effusion. He said that the microscopical examination of the fluid was very important, for in this way it could be determined whether the condition was of tuberculous or inflammatory origin or whether it was merely dropsical.

BRISTOL MEDICO-CHIRURGICAL SOCIETY. — A meeting of this society was held on Jan. 13th, Mr. J. Paul Bush being in the chair.—Dr. H. Elwin Harris showed a case of Congenital Absence of the Left Auricle and External Auditory Canal with Facial Paralysis.—Mr. H. F. Mole showed (1) patients on whom the Radical Mastoid Operation or Ossiculectomy had been performed for the cure of chronic suppuration in the middle ear; (2) a patient on whom Choledochotomy had been performed; (3) a specimen of a Tumour growing from the cartilaginous septum of the nose; and (4) a Skiagram of an Unusual Dislocation of the Ankle.—Dr. J M. Fortescue-Brickdale showed a specimen of a Cyst below the liver, apparently an accessory gall-bladder, and the Brain of a child showing simple meningitis and considerable dilatation of the ventricles.—Mr. James Taylor showed a skiagram from a case of Scurvy Rickets.—Dr. E. W. Hey Groves read notes and showed the specimen of a case of Tubal Gestation producing severe internal hæmorrhage without rupture.—Mr. W. Roger Williams discussed the case.—Dr. W. K. Wills read a paper on the Present Position of Radiography in Therapeutics.—Mr. Bush, Dr. Harrison, Dr. P. Watson Williams, and Mr. Taylor discussed the paper.—Dr. Theodore Fisher read a short paper on Hæmatemesis associated with small white kidneys.—Dr. Watson Williams, Dr. E H. E. Stack, and Dr. J. A. Nixon made remarks on the cases.

SOUTH-WEST LONDON MEDICAL SOCIETY.—The monthly meeting of this society was held on Jan. 13th, Mr. E. F. White, the President, being in the chair.—Mr. J. H. Targett read a paper on Some Difficult Cases of Uterine Hæmorrhage and exhibited specimens illustrating the lesions described. The cases were grouped under the following headings: (1) Hæmorrhages occurring in very early pregnancy; (2) post-climacteric hæmorrhage; and (3) hæmorrhages due to general disorders, such as chronic alcoholism, Bright's disease, and the like.—After the reading of the paper a discussion took place to which several members of the society contributed.—At the close of the meeting the general business of the society was transacted.

Reviews and Notices of Books.

The Lymphatics. In two Parts: 1. The General Anatomy of the Lymphatics, by G. DELAMARE. 2. The Special Study of the Lymphatics in Different Parts of the Body, by P. POIRIER, Professor of Anatomy, and B. CUNÉO, Professor (*agrégé*) to the Faculty of Medicine of Paris. Translated and edited by CECIL H. LEAF, M.A., M.D. Cantab., F.R.C.S. Eng, Assistant Surgeon to the Cancer Hospital. With 117 Illustrations and Diagrams. Westminster: Archibald Constable and Co., Limited. 1903. 8vo, pp. 301. Price 18*s*. net.

DURING the last 12 years a monumental work on anatomy has been slowly but steadily progressing in France under the able direction of Professor Paul Poirier of Paris, with the collaboration of Professor A. Charpy of Toulouse, Professor A. Nicolas and Professor A. Prenant of Nancy, and Professor T. Jonnesco, prosector to the Faculty of Paris. Four large volumes, averaging 1000 pages each, have appeared and only the part devoted to the senses remains to complete this splendid treatise. The section on the lymphatics belongs properly to the second volume long since published but its appearance has for some reason been delayed and Professor Poirier, finding that he was unable to write the description of the general anatomy and histology of the lymphatic system, intrusted it to Dr. Gabriel Delamare, reserving for himself and Professor Cunéo the special study of the lymphatics of the different parts of the body. The whole section, which appeared in 1902, has now been translated into English by Mr. Leaf, and after comparing many pages of the translation with the original we congratulate him on having rendered the French into English with great accuracy and on presenting to his countrymen an excellent account of the present state of knowledge of the lymphatics as it is taught and understood in France.

The general anatomy of the lymphatics, written by Dr. Delamare (unaccountably written Delamere in the title page of Mr. Leaf's translation and in the editor's preface, and again at the heading of the article), commences with a description of the leucocytes of the blood, their movements and reproduction, and the action of staining agents upon them The microcytes and macrocytes, and finally the cells of Ehrlich, are considered in succession. The microcytes, which are of about the size of red blood corpuscles, have received many names. They are the free nuclei of Robin, the lymphocytes of Einhorn and Ehrlich, and the leucoblasts of Denys; they are not phagocytes and have only a limited power of movement. They are found normally in the blood and lymph, the lymphatic glands, the spleen, and the red marrow of bones. By the concurrent estimates of several good observers they constitute about 25 per cent. of the white corpuscles of the blood. Dr. Delamare himself found in the fluid taken from the thoracic duct of the dog (he does not specify whether after food or in the fasting state) that out of 133 elements 128 were microcytes The macrocytes or macrophages of Metchnikoff are of much larger size; they are amœbic and extremely phagocytic. They digest the bacillus of Hansen, red corpuscles, leucocytes, and even particles of sulphate of arsenic. In the enumeration given by different observers their number varies from 1 to 13 per cent. of the leucocytes. They are found in the blood and lymph, the lymphatic glands, the spleen, and the bone marrow. The third form of white corpuscle or cell with neutrophile granules is the polynuclear leucocyte or leucocyte with a polymorphous nucleus of Metchnikoff. It constitutes about 70 per cent. of the leucocytes of the blood. These corpuscles are very amœbic and very phagocytic. Other forms of cells described by Dr. Delamare are the cells with acidophile granules, the alexocytes of Kanthack and the eosinophiles of Denys. The phagocytic power and amœbic movements of these leucocytes are feeble. Lastly, there are the basophile granules—metachromatic cells or cells of Ehrlich. All these are fully described by Dr. Delamare with abundant references to the opinions of the numerous observers who have spent so much time in the elucidation of these objects and who have still left so many points obscure

The second part of the book, by Professor Poirier and Professor Cunéo, is much longer than the first and gives an account of the distribution of the lymphatics of the different organs of the body. This is illustrated by many beautifully executed woodcuts and we have not seen any account of the lymphatics of the pelvis approaching in precision that here given. It will prove of special interest to obstetricians, since the lymphatics of the uterus, the vagina, and the adjoining parts are given in great detail. The chyle vessels are not described on account of their structure being relegated to another volume of the "Anatomy" of Professor Poirier and Professor Charpy. We are rather surprised that amongst the numerous names given in the text and in the very large bibliography that of Dr. Ludwig Teichmann should be missing, since his figures were not only very accurate but are the source of many of those that adorn our text-books. Professor Poirier and Professor Cunéo give the proceedings that have been adopted by many anatomists and histologists to inject the lymphatics, together with an account of the fluids employed, which have been very various, including among others mercury, wax, oil, a saturated aqueous solution of Prussian blue, gelatin, and turpentine. A due meed of praise is given to Gerota's method, in which absolute black, extractum alkannæ, and cinnabar in addition to Prussian blue are used. Enough has been said to show that this work on the lymphatics will prove useful to the anatomist, the physiologist, and the practitioner.

A Guide to the Housing Acts, with Appendices containing the Statutes affecting Housing 1882–1903, together with the Forms and Circulars of the Local Government Board. By ARTHUR P. POLEY of the Inner Temple and Midland Circuit, Barrister-at Law. London: Eyre and Spottiswoode. 1903. Pp. 409. Price 3*s* 6*d*.

LOCAL authorities in exercising the important and useful powers given to them by the Housing Acts find that the principal Act which they are charged to administer (the Housing of the Working Classes Act, 1890) has in the 13 years of its existence been supplemented by no less than six minor Acts, passed with a view to make clearer or to amend its provisions. Members of county and borough councils may, therefore, well require a handy volume containing not only the Acts in question but full explanations of their working. Mr. Poley's volume fulfils these conditions; it is of a size adapted to the pocket and it contains all that is necessary for those desiring to understand as far as possible the business details of the Acts as well as the general scope of their provisions. They are not statutes easy to master or to carry out and it is to be hoped that some day means may be found to render the procedure for the object in question more simple and more uniform. Mr. Poley calls attention to the fact that three schemes of compensation are provided under Parts I., II., and III. of the principal Act necessitating references to a special scheme for compensation under the schedule to the Act with reference to Part I., and references to other Acts of Parliament under Parts II. and III., with the additional complication of procedure that may be entailed by utilising Part III. in conjunction with Part I. or with Part II. There are differences also, to quote another instance of complication, between the schemes known as improvement schemes and those termed reconstruction schemes. The same authority carries out both in cities, including that of London, in boroughs and in urban districts, but not in the county of London, where the County Council undertakes the former and the borough councils are responsible for the latter. All these and many others are matters of which individual members of councils should have knowledge if they would take an active part in the improvement of the conditions of life among the poor and the working classes which Housing Acts are intended to promote. Apart from such interest as medical men may take in their local public affairs they are directly concerned in the Housing Acts where they are medical officers of health, and in London they may be specially appointed medical officers of health by the County Council for the purposes of the Housing Acts. In addition to this, when 12 or more ratepayers are dissatisfied with the attitude of a medical officer of health with reference to an area which they believe to be unhealthy, a medical practitioner may be called upon to inspect the area complained of and to report as to its condition in his opinion. In all circumstances in which medical men are required to act under an Act of Parliament it is useful, if not necessary, that they should fully inform themselves as to the powers thus vested in them, and with regard to the Housing Acts Mr. Poley's book seems to afford the requisite information within a convenient compass, together with such as may be required by surveyors, solicitors, and others.

Diseases of the Eye: a Handbook of Ophthalmic Practice for Students and Practitioners. By G. E. DE SCHWEINITZ, A.M., M.D., Professor of Ophthalmology in the University of Pennsylvania. With 280 Illustrations and six Chromo-lithographic Plates. Fourth edition. London and Philadelphia: W. B. Saunders and Co. Large 8vo, pp. 773 Price 21*s*. net.

WE had occasion when reviewing the first edition of this work in 1892 to speak of it in favourable terms. The author holds responsible positions and has had large experience to guide him in his descriptions of disease and of the various modes of treatment tried by himself or suggested by others. That experience he has utilised in the successive editions of his treatise which have appeared and in its present state it may be regarded as containing in moderate compass all that the practitioner needs to know in this department of medicine. Like the majority of American works on ophthalmology the optical principles concerned in vision, the conditions of normal and abnormal refraction, and the disturbances of motility, as well as the operations on the eye and its appendages are treated with great fulness of detail, and the illustrations are not only very numerous but amongst the clearest and best that have been published. Many important additions have been made in the present edition, such as a description of Dr. W. Thomson's lantern test for colour blindness which should be employed by all those who have charge of the vision of railway servants, sailors, signalmen, and others; the ophthalmoscopic signs of general arterio-sclerosis; the significance of optic neuritis; the educative treatment of strabismus; and many others to which attention has been drawn of late years.

In discussing the propriety or wisdom of removing the lens in degrees of myopia amounting to 15 D. or more Professor de Schweinitz states that although his experience has been very limited it has been [illegible] the [illegible] the operation. The list of dangers which he appends is sufficiently formidable to prevent most men from undertaking the operation without much consideration and without strong motives such as the advance of the disease or great deterioration of vision, for it includes intraocular hæmorrhage, detachment of the retina, iritis, and infection of the corneal wound. The latter complication if due precaution is taken ought to be excluded; the others, however, are not only extremely dangerous but are only to a limited extent under the control of the operator. The rule here laid down for the ordering of glasses in myopia is that young people under 20 years of age with good vision and a moderate degree of myopia—that is to say, under 5 D.—should wear the *full* correction *constantly*, providing that the accommodation is ample and that no signs of fatigue are evident. A short chapter might with advantage have been added to this otherwise very excellent work on the medico-legal relations of the diseases and injuries of the eyes.

Studies in Comparative Odontology. By A. S. UNDERWOOD, M.R C S. Eng., L.D.S. London: Baillière, Tindall, and Cox. 1903. Pp. 153. Illustrated. Price 5*s.*

THIS is an excellent little work and is full of interest from beginning to end. Mr. Underwood has the happy knack of being able to fix the attention of his readers and the evident enthusiasm of his style cannot fail to show students, who often regard odontology as useful only for examination purposes, that it may in reality be fascinating in a high degree. His main object has been to impart sound ideas as to the broad, underlying principles of the subject, leaving the student to fill in details from more comprehensive treatises, and he trusts, to use his own expression, that a new way of putting things and a new way of looking at them may lead to a better appreciation of those standard works. In clear, concise terms he has enunciated the general terms used in odontology, the methods by which teeth of complex type have been evolved from those of more simple pattern, and the different modes by which teeth are attached. In successive chapters the odontology of the different classes of the vertebrata is described. General characteristics are narrated, a description of each order is given, and typical examples are taken. Many problems perplexing to students are solved by the introduction of suitable diagrams, instances of which will be found in the description of the gymnodonts and the development and the mode of erection of the poison fang of viperine snakes. The concluding chapters of the book on the Effects of Environment upon Animals and the Chain of Life are clearly and simply written.

JOURNALS AND MAGAZINES.

Journal of Anatomy and Physiology. Conducted by Sir WILLIAM TURNER, K.C.B., F.R.S., D. J. CUNNINGHAM M.D., F.R.S, G. S HUNTINGTON, M.D., A. MACALISTER, M.D., F.R S., and J. G. M'KENDRICK, M.D., F.R.S. Vol. XXXVIII. Part 2, January, 1904. With Plates and Figures in the text. London: Charles Griffin. Price 6*s.*—The contents of this part are: 1. A Comparative Study of the Grey and White Matter, of the Motor cell Groups, and of the Spinal Accessory Nerve in the Spinal Cord of the Porpoise (*phocæna communis*), by David Hepburn, M.D. Edin., professor of anatomy, University College, Cardiff, and David Waterston, M D. Edin., senior demonstrator and lecturer on regional anatomy, University of Edinburgh, with four plates. The authors of the article state that the maximum superficial area of a section of the cord of a porpoise was at the level of the seventh cervical vertebra; the next largest area was about the seventh lumbar enlargement. The areas of the columns of grey and white matter vary in their relative proportions in different regions and just as the posterior columns do not increase uniformly in size from below upwards so neither do the anterior and lateral columns diminish uniformly from above downwards. Many of the fibres in all the columns act as longitudinal commissural bands between different segments of the cord. The grey matter is arranged in two comma-shaped masses, united by a commissure. The illustrations show the form of, and the area occupied by, the grey matter at different levels The article is a valuable contribution to our limited knowledge of Cetacean neurology. 2. Skulls from the Round Barrows of East Yorkshire, by William Wright, F.R.C S. Eng., with a plate. The author gives a description and the measurements of 16 skulls. 3. The Varieties of the Os Calcis, by P. P. Laidlaw, B.A., Scholar of St. John's College, Cambridge, with five plates. 4. Further Observations on the Functions of the Spleen and other Hæmolymph Glands, by Thomas Lewis, with a plate. 5. A Note on an Exceptional Human Brain presenting a Pithecoid Abnormality of the Sylvian Region, by G. Elliot Smith, M.D. Sydney, professor of anatomy, Cairo. 6. A Note on the Communication between the Musculo-Spiral and Ulnar Nerves, by G. Elliot Smith, M.D. Sydney. 7. A Note on the Fossa Parieto-Occipitalis, by G. Elliot Smith, M.D.Sydney. 8. The Insertion of the Pyriformis and Obturator Internus and Formation of the Posterior Circular Capsular Fibres and Upper Retinaculum of Weitbrecht, by J. Ernest Frazer, F.R.C.S. Eng., with figures in the text 9. An Abstract of Lectures on the Early Stages in the Development of Mammalian Ova and on the Formation of the Placenta in Different Groups of Mammals, by Arthur Robinson, M.D. Edin., with two plates. 10. The Germ Cells: Part I., continued, by John Beard, D.Sc. 11. The Proceedings of the Anatomical Society of Great Britain and Ireland.

Looking Back.

FROM

THE LANCET, *SATURDAY*, JAN. 21, 1826.

MEETING OF THE STUDENTS
AT
ST. BARTHOLOMEW'S HOSPITAL.[1]

A Meeting of the Students of this Hospital took place in the Anatomical Theatre, on Wednesday se'nnight, for the purpose of taking into consideration the propriety of requesting the surgeons to allow the name, age, disease, and principal treatment of every patient under their care, to be affixed to a convenient part of the bed. It is scarcely necessary to observe, the most intense interest was excited in consequence. Immediately after the afternoon lecture, Mr. Skey was called to the chair, when the following resolutions, addressed to the surgeons, (which had been previously drawn up by one of the students, Mr. Turley), were proposed and carried unanimously.

1st. That for the benefit of the students and the economy of your time, the name, age, disease, and treatment of each patient be posted on some conspicuous part of his bed.

2d. That all accidents admitted, be registered every day in a book kept for the purpose in each accident ward.

3d. That a notice of all operations to be performed should be pasted on the board in the Anatomical Theatre.

Here some desultory conversation arose previous to putting the fourth and last resolution, and which, indeed, was not embodied with the foregoing; it was as to the mode of conducting post-mortem examinations, and the shameful extortion of sixpence from every pupil entering the dead house.

---

[1] Only a portion of the account of the meeting has been transcribed.

THE LANCET.

LONDON: SATURDAY, JANUARY 23, 1904.

The Relations of the General Practitioner to the Consultant.

Consultants have their uses whether they practise as general physicians, as operating surgeons, or as specialists. The general consulting physician or surgeon almost invariably holds a post which entails upon him huge and varied experience. To the specialist it is given by special study of one branch, or segment of a branch, of medical science to gain more knowledge of that department of practice than is vouchsafed to the average medical practitioner. Those members of the profession who are in general practice have to treat patients suffering from ailments belonging to medicine, surgery, and gynæcology, and the very fact that their knowledge has to be so wide prevents its reaching so great a depth in particular directions as is attainable by those who see disease marshalled before them in the wards of great hospitals, or who study one small portion of the vast field of medical knowledge under exceptionally favourable circumstances. As a means of advancing the science of medicine and of affording assistance in diagnosis and treatment in cases of special difficulty the consultant is of inestimable value. But the general practitioner is the backbone of the profession as we have always maintained. To vary the metaphor, the consultants may be looked upon as the vanguard of the advancing hosts of medicine, whilst the general practitioners compose the main body on whom devolves the greatest share of the fighting. By itself the vanguard could not hold its own; unsupported by the vast army of those in general practice it could not stand. This support of the consultant by the general practitioner has always been recognised by the leaders of the profession. In the first number of The Lancet, published now more than 80 years ago, we reported Sir Astley Cooper's acknowledgment that it was to the general practitioners with whom he was acquainted that he owed his position more than to any merit of his own. Without attaching too much importance to Sir Astley Cooper's disclaimer of merit we may accept the general statement of his indebtedness to those in general practice, adding that the real heads of the medical profession at the present day in most instances hold their position on the same ground. The consultant is, on his side, of value to the general practitioner. In a difficult case—difficult either in diagnosis or in treatment—what can be more helpful than the opinion of one who has devoted special attention to the subject or who is known to enjoy great opportunities of experience? Even if the verdict be that nothing can be done—that the resources of science are exhausted—there is a consolation both to the friends of the patient and to his medical attendant that they have had the opinion of one well qualified to judge.

Disputes, or rather causes of friction, frequently arise between consultants and general practitioners, and when they do the reason is either that the report given to the general practitioner by the patient as to the opinion of the consultant is incorrect, or that the general practitioner thinks that the consultant has tried to oust him from medical attendance. With the best will in the world to describe what has taken place and what has been said, the patient may misrepresent what has occurred. Therefore it is well for the consultant never to send verbal messages by the patient if it can be avoided. If any message must be sent by the patient it should be couched in the simplest words and phrases. All important communications should be in writing and then there can be no possible ground for misunderstanding. The practitioner is entitled to a full account of the consultant's opinion. The consultant should be especially careful in what he says to the patient of the treatment pursued by the medical man who has already been in attendance. To find fault with what has been done is in the highest degree reprehensible, for the general practitioner is in consultation with the specialist, even though he may not be present in person. It is not only undesirable for the patient's sake to shake his faith in his medical attendant, but it is unfair, and even dangerous, to do so without hearing what the medical attendant may have to say. The harm that may be done in this way is incalculable. The other great cause of friction between the consultant and the general practitioner is the belief that more than occasionally the former takes possession of the patient of the latter. We trust that this is rare in reality, but we fancy that there is a widespread belief among general practitioners that some consultants habitually act thus, although attempts to obtain public support in such a base manner must ultimately defeat themselves with ignominy. We have been led to make these observations by the letter and inclosure which will be found on p. 254). This communication may be summarised as follows. A general practitioner living a few miles from London had a patient suffering from a prostatic calculus. There were no urgent symptoms and therefore an attempt was made to lessen the size of the stone by internal medication, so that it might come away per urethram. (This was perfectly legitimate treatment, though, of course, not to be persisted in after a reasonable time.) The attempt to diminish the size of the stone did not appear to be successful and the advice of a consultant was sought, the general practitioner making the appointment and supplying the consultant with a full history of the case. The patient went to London, interviewed the consultant, and the diagnosis was confirmed. But according to the patient's statement the consultant pointed out the great danger of delay, saying that the general practitioner had acted wrongly in treating it medically, and urging immediate operation. The patient arranged to enter a public hospital to which the consultant was attached on the following day. Now comes the most surprising portion of the allegation. The patient was made to promise to send a fee of 20 guineas for the operation to the consultant that same night, although he was to be an inmate of a public hospital, and of this monetary transaction no one was to be told. No letter was written to the general practitioner and the only message was that the consultant was too busy to write but that a large stone was present "which should not have been left so long." The patient went home; on his way he called on his medical man and faithfully delivered the consultant's message. The same night he sent off the 20 guineas. So far, of course, we have only an *ex parte* statement and one made by a man who takes no pains to conceal that he considers himself aggrieved. But something depends on the accuracy of the patient's memory who may have misunderstood the consultant. Two facts, however, seem to be clear: one is that the patient was told that there was a large stone present which should have been removed before. This was utterly unfair to the general practitioner; such extreme urgency is not present in a case of prostatic calculus unless it is definitely causing retention of urine and no such symptom was present. The other fact, a highly disagreeable one, is the demanding of the 20 guineas to be sent by post the same night. It does not seem possible that there can be any mistake in this matter, for the money was sent. We do not quite understand how the consultant could demand a fee for an operation to be performed in a public hospital, but possibly it may be permitted in the hospital to which he is attached. If it is permitted the sooner the rule is altered the better for the institution. Here we have the two causes which we have mentioned as originating frequent disputes between consultants and general practitioners. The consultant is alleged to have criticised adversely the general practitioner's treatment to the patient, and appears to have attempted to annex the case.

Now comes the poetic justice. In the early morning following the journey to London the patient was seized with retention of urine, his own medical man was sent for, and before he arrived the stone was passed. Possibly the consultant's examination had slightly displaced it; perhaps the double railway journey had assisted to this fortunate issue. The eroded surface of the stone showed the solvent action of the treatment already employed, and thus the internal medication must be credited with assisting in the happy issue of the case; but whatever may have been the cause the fact remains that the *fons et origo mali* has been expelled. And just about the time of the delivery of the calculus the London consultant is receiving the cheque. The mind of the patient thinks with natural regret of the money sent in vain. Not a syllable of the pecuniary transaction has he yet breathed to anyone but his heart misgives him and he confesses to his medical man what he has done. Fortunately, the cheque is returned on application but the careful consultant sends with it the advice that should any hæmaturia or difficulty of micturition at any time occur the patient should return to town at once. The general practitioner who had applied to the consultant for advice has to content himself with the meagre but eloquent message brought to him by the patient, amounting to an accusation that he had misjudged the case. Not a single written line does he ever receive from the consultant. Even after allowing for some errors in the patient's statement sufficient evidence remains to show that the general practitioner has been gravely wronged. In no point, in our opinion, did the consultant act correctly towards the medical man who had applied to him for an opinion. It may reasonably be asked, What should a consultant do when he finds that the general practitioner has made a mistake in diagnosis or treatment? The decision is clear. The consultant is asked to suggest the treatment to be pursued; he has to deal not with the past but with the future, and he is not justified in making unfavourable comments to the patient on the conduct of the general practitioner who has called him in consultation. He may say what he likes to the general practitioner, but there should be no antagonism between general practitioners and consultants, for they are necessary to each other The family adviser has facilities for observing a patient which are denied to the consultant; he "knows his patient's constitution," as the phrase goes, and there is an important truth in this; he knows which organs are specially prone to be affected; he knows his patient's idiosyncrasies as to diet and drugs, and as years go by we are learning to appraise this knowledge more highly than formerly. That general practitioner is wisest who recognises when he needs a further opinion; that consultant is wisest, even as worldly matters go, who recognises that the patients sent to him are not his patients unless they are specially given over unto his care and who deals with those who send him patients as he would wish to be dealt with were the positions reversed. Such mutual trust will not merely be best both for the consultant and the general practitioner but will also be for the best interests of the patient who commits his health and life to their care.

◆

Sight Testing by Opticians.

WE have had occasion at various times during the last tw or three years to refer to the endeavours of a certain sectio of the spectacle trade to set up a new form of quackery i relation to the prescribing of glasses, and to assume t themselves a position which nothing short of a complet medical and surgical education could by any possibilit justify. We have not hesitated to condemn these endeavour in the plainest terms; and our views concerning them have been confirmed by the authority of the Presiden of the Royal College of Surgeons of England in th address which he lately delivered as President of th Ophthalmological Society. We have therefore the mor pleasure in calling attention to a letter which has bee sent to the leading journals of the optical trade b Mr. W. A. DIXEY, a well-known spectacle-maker an optician. In this letter, from the point of view of th interests of the trade itself, he strongly enforces th arguments which, in the interests of the public, we hav found it necessary to employ. The letter has bee called forth by a proposal to add the subject of "sigh testing" to the examinations for opticians held by th Spectacle Makers Company, and by the circumstance th the court of the Company has appointed a committee t inquire into, and to advise upon, the question. Mr. DIX is strongly opposed to the suggested course and he rest his opposition upon three principal grounds. The first i that medical knowledge and training are necessary for prope sight testing and that outside the medical schools no facil ties exist for their acquirement. The second is that th "convention" of the consulting room is better suited to sigh testing than is that of the shop and that the addition of a sight-testing qualification to the certificate of the Company would therefore be undesirable. The third is that such an examination would be against the best interests of the trade, and would tend to divert the energy of optical students from the practical side of their work and to endanger the usefulness of the present examinations. These reasons, so far as the medical profession is concerned, remind us of those which were once produced to the Lord Chamberlain by a deputation from the mayor and corporation of a country town who desired to anticipate a possible charge of disloyalty for not having caused the parish bells to be rung upon the King's birthday. The deputation assured his lordship that they had twelve sound and sufficient reasons for the course which had been pursued and the first of them was that there were no bells in the parish. The second—but here the Lord Chamberlain interrupted them, declaring that the first alone would abundantly satisfy His Majesty and that he would not trouble them to proceed further with their discourse. We have every desire for the prosperity of the spectacle trade so long as the proceedings of its members are confined within proper limits, and we are convinced that Mr. Dixey is an excellent judge of the means by which that prosperity may most effectually be promoted. We are therefore quite prepared to agree with the whole substance of his contention; but his first argument is that upon which we rely. We have no doubt that his experience has brought under his notice a good many cases in which serious harm has followed from the use of spectacles prescribed by persons who had not received "medical knowledge and training" and we heartily congratulate him upon the courage and wisdom which his letter has displayed. It is so much more easy for any man in an assured position to go with the stream than to oppose himself to ignorant agitation, that a conspicuous instance of the latter course ought not to pass unnoticed by those who are competent to estimate it rightly. We sincerely hope that the court of the Company will be convinced by Mr. Dixey's arguments, and that a very mischievous proposal may be rejected by a sufficient majority to prevent its early reappearance. If the Company will use its influence to restore and to improve the manufacture of spectacles in the United Kingdom, it will be likely to accomplish far more for the encouragement of the trade than can ever be done by encroachments upon the province of the medical practitioner.

Sleeping Sickness.

In an annotation in The Lancet of Sept. 12th, 1903, p. 769, we referred to the Progress Report issued by the commission which was despatched to Uganda by the Royal Society to investigate the cause and modes of conveyance of sleeping sickness. Most valuable work has been accomplished by the members of that commission and their predecessors, and in our issue of Dec. 19th, p. 1730, we printed a *résumé* of a "Further Report on Sleeping Sickness in Uganda" which has recently been published. Unfortunately, some correspondence has appeared in the *Times* with regard to priority in the discovery of the cause of sleeping sickness. Doubtless honour should be given to whom honour is due and in the present instance praise should be accorded to all those who, heedless of danger, have given assistance in arriving at the results which have already been attained. In 1902 Dr. A. Castellani discovered a bacterial parasite—a streptococcus—in cases of sleeping sickness and after painstaking investigations stated as his opinion that this organism was the cause of sleeping sickness. He subsequently found a trypanosome in a case of sleeping sickness but did not then attribute any causal relationship between that organism and the disease. On the arrival of Colonel D. Bruce, R.A.M.C., F.R.S., in March of last year, Dr. Castellani still maintained his streptococcus theory, but after mentioning to Colonel Bruce that he had found trypanosomes in five cases of the disease the former urged him to make further investigations, with the result that he found the organisms in 70 per cent. of the cases examined. This naturally led to a reconsideration of his streptococcus theory and he then suggested that sleeping sickness is due to a species of trypanosomes and that at least in the last stages there is a concomitant streptococcus infection which plays a certain part in the course of the disease. To Dr. Castellani must be given the credit of being the first to demonstrate the presence of the trypanosomes in cases of sleeping sickness and also of introducing the method of centrifuging the cerebro-spinal fluid in his search for the streptococcus. Colonel Bruce, on the other hand, originated the theory that the trypanosomes might cause the disease. We trust therefore that there will not be any further controversy as to priority and that to all concerned in this most important inquiry will be accorded the thanks which they deserve.

The discovery of trypanosomes in the blood of human beings had been previously made by Dr. J. E. Dutton in 1901, and in a recent issue[1] we published a brief review of the "First Report of the Trypanosomiasis Expedition to Senegambia (1902) of the Liverpool School of Tropical Medicine and Medical Parasitology." This has been compiled by Dr. Dutton and Dr. J. L. Todd, who were sent to Senegambia to make certain investigations. They only found six cases of trypanosomiasis in the natives but state their reasons for considering that the percentage of infection given by these figures is smaller than is actually the case. From the clinical description given of the cases lethargy is not a prominent symptom. The observations of Colonel Bruce and his colleagues prove definitely, however, that trypanosomes are always present in the cerebro-spinal fluid of patients suffering from sleeping sickness and that there is also strong ground for believing that there is a close connexion between the so-called "trypanosoma fever" and sleeping sickness. They also show that the disease can apparently be transferred from human beings to monkeys by means of inoculation. It was further shown that the distribution of sleeping sickness coincides with the distribution of a *biting insect—a tsetse fly, the glossina palpalis*. This most important fact at once suggested that the disease was communicated by means of this fly and corroborative evidence was adduced by means of allowing flies confined in a cage to feed on patients suffering from sleeping sickness and at varying intervals to place the same cage of flies on monkeys. Positive results were obtained. Tsetse flies were then freshly caught and placed at once on healthy monkeys; the results were again positive.

---

[1] The Lancet, Dec. 19th, 1903, p. 1727.

From the above facts there is strong reason to suppose that sleeping sickness is a disease transferred from man to man by means of the tsetse fly, but according to remarks made at recent meetings of the Epidemiological Society on Dec. 11th and Jan. 15th[2] it is evident that absolute scientific proof is still wanting. The general tone adopted by the speakers was certainly in favour of the correctness of the theory just enunciated. Dr. L. W. SAMBON drew attention to the significant fact that the flies freshly caught conveyed the disease to monkeys in two or three weeks, whilst in the case of those which had previously fed on patients the symptoms did not appear for about eight weeks, thus suggesting that the flies were more active in directly conveying the disease than in transferring it from man to man. Dr. D. NABARRO, in a most interesting speech, explained this difficulty by detailing the manner in which the experiments were carried out. The fresh flies were brought into the camp during the day, kept over night, and then put on a monkey. Being hungry all the flies fed well and thus the animal was placed in a favourable condition for infection and the organisms speedily appeared in the blood. In the other series of cases in which flies were first fed on patients suffering from sleeping sickness and then on monkeys, the animals were not so strongly exposed to infection, since the flies did not feed so well or so numerously as the patients frequently removed the flies before a full meal had been taken. Sir PATRICK MANSON, whilst believing that the cause of sleeping sickness had been discovered, nevertheless maintained that the scientific chain of evidence would not be complete until pure cultures of the organisms had been obtained and further tests had been made with those cultures. In support of this suggestion he stated that the experiments of injecting blood or cerebro-spinal fluid of patients infected with sleeping sickness and subsequently inducing the disease in the monkey were not conclusive in establishing an etiological relationship between the trypanosomes and sleeping sickness, since some other organism might have been simultaneously injected. Dr. F. W. MOTT, from his own experiments, laid more stress on the streptococcus infection which Dr. CASTELLANI was the first to demonstrate. During the discussion a case was frequently mentioned which Sir PATRICK MANSON had observed in this country (the patient having previously been in infected districts) and which had proved fatal. Dr. MOTT had isolated a diplococcus from the enlarged glands and in his opinion the diplococcus infection had precipitated the onset of the symptoms. To sum up the results of this discussion we may repeat that although the general tone indicated a belief that the trypanosomes were the cause of sleeping sickness yet there was a strong feeling that further scientific investigation was required before the etiology could be considered as entirely settled. In this view we concur.

In conclusion we desire to draw attention to the discrepancy between the terminology which appears in the printed version of the report presented to the Royal Society by its commissioners and that adopted at the discussion at the Epidemiological Society. In the former we find the parasite called "trypanosome," with the plural term "trypanosomes," whilst the speakers at the latter society adopted the terms "trypanosoma" and "trypanosomata." It would be well, we think, if some decision were come to whereby uniformity might be preserved.

◆

The Medical Profession and the Dispensing of Medicines.

WHATEVER opinion may be formed upon the broad lines of the Draft Medical Act Amendment Bill which has been prepared by the medico-political committee of the British Medical Association, we believe that the new clauses, which are to be considered at a general meeting of the Metropolitan Counties Branch, will scarcely be received with enthusiasm by many country practitioners. The Bill, the general scope of which is familiar to many of our readers, proposes a reconstitution of the General Medical Council, with a very great reduction in the numbers of members nominated by the different examining bodies and with a great increase in the numbers of Direct Representatives to be elected by the registered medical practitioners resident in various parts of the United Kingdom. It is proposed that the Direct Representatives and the nominated members of the Council should be numerically equal and that in addition there should be five Crown nominees, three for England, one for Scotland, and one for Ireland. To this composite body are to be intrusted the registration of students and of practitioners and penal powers analogous to those at present possessed by the General Medical Council. But the new General Medical Council is, according to the Bill, also to have the power to appoint assistant examiners for the various intermediate examinations, inspectors to visit medical schools or hospitals who are to report upon their suitability for affording adequate instruction, and the privilege of itself appointing boards of examiners in medicine, surgery, and midwifery to conduct a State examination qualifying for registration in these subjects. This examination, it is proposed, should be held simultaneously in London, Edinburgh, Dublin, and at such centres of medical education as the Council may from time to time determine and is apparently intended to be the sole qualification for registration. The fee for initial registration is to be only £1, but a further annual payment of £1 will be required for the privilege of being entered on the Register each ensuing year. It will thus be seen that the Bill proposes large measures of medical reform. The existing poverty of the General Medical Council is to be removed by the creation of an annual income, while its position as the central authority in medical education is to be confirmed; and the much wanted one-portal system is to be introduced.

Much could and will be written on this Bill, but at the present moment we propose only to notice certain new clauses which are to be discussed at the meeting of the Metropolitan Counties Branch of the British Medical Association. Both clauses deal with questions that concern the medical profession as a whole, while to one of them our attention is drawn pointedly by a correspondent. The first clause appears to be dictated by the desire to show that practitioners will obtain something for their money besides the insertion of a line in the Register. It is as follows:—

---

[2] For reports of these meetings see THE LANCET, Dec. 19th, 1903, p. 1721, and p. 228 of our present issue.

> "Any person registered under this Act shall, by right alone of such registration, be eligible to all appointments in the United Kingdom, which may be held by a legally qualified medical practitioner."

But this really promises nothing, since those who elect will surely cling to the tradition of appointing the man who appears to be best qualified. The clause is redundant, since no one is a legally qualified medical practitioner unless registered, and no one, if this Bill passes, can in the future be registered without passing this State examination in medicine, surgery, and midwifery. A second clause is more impracticable, though on a first reading its intention to raise the tone and tatus of the medical profession may disarm criticism. It is:—

> "No person registered under this Act, excepting only as hereinafter indicated, shall dispense or supply drugs or other medicaments to anyone."

Before considering the exceptions we would plead for a little greater precision of the terms employed. If such an enactment had been in force when KOCH'S tuberculin was first introduced into this country would a practitioner have been breaking the law when daily employing the "drug or other medicament"? If in the future some similar treatment is suggested for disease where there is no question of emergency would penalties be incurred under this clause? It may be assumed that in the desire to check the practice of dispensing by medical men these contingencies have not occurred to the author of this clause. The list of medical men to whom the operations of the clause are not to apply, and who will therefore escape the risk of a suggested penalty of £100, is sufficiently curious:—

> "1. Medical officers of H M.'s navy or army not engaged in private practice. 2 Registered practitioners while in attendance on cases of emergency requiring in the opinion of the practitioner the immediate use of a drug or ther medicament. 3 Registered persons practising their profession in country districts in which the inhabitants are so few that they cannot support at the same time both a medical practitioner and a pharmaceutical chemist."

How is the medical man to ascertain the supporting power of his district except by bitter experience? It almost suggests a melancholy picture of the survival of the fittest, and yet the author goes on relentlessly:—

> "It shall nevertheless be incumbent upon any medical practitioner so practising in such a country district to satisfy the General Medical Council, when called upon by that body so to do, that the people of the country district in which the practitioner is engaged in medical practice and in the dispensing of drugs or of other medicaments are, in fact, too few in numbers to support both a medical practitioner and a pharmaceutical chemist."

This would surely entail an amount of vexation sufficient to deter many from venturing into country practice and it would involve lengthy sittings of the General Medical Council in search of information as to the population and wealth of rural districts. We cannot conceive the General Medical Council turning itself into a kind of tariff commission. The last two exceptions are:—

> "4. Medical practitioners employed on board of vessels other than H.M.'s ships. 5. Any other person registered under this Act, the peculiar circumstances of whose professional work require in the opinion of the General Council, before which the facts must be brought, special consideration with a view to the exemption of such person from the action of this clause."

In other words, with authoritative permission, and after due inquiry, this clause may be set aside with all its terrors of a fine of "not less than One Hundred Pounds" and the threat of removal from the Medical Register.

That such proposals should be gravely put forward for discussion appears to argue great lack of appreciation of the conditions of practice not only in country districts but also in the poorer quarters of our large towns. While the clause appears to be directed solely towards the extinction of the dispensing medical man, it would operate by fostering the growth of the prescribing druggist. The proposals of the Draft Medical Act Amendment Bill are sufficiently striking and revolutionary without these two suggested clauses. Should the clauses be carried by the Metropolitan Counties Branch there can be no doubt that they will rouse a critical interest in the Bill which may check the further action of those who desire the one-portal system and increased direct representation.

Annotations.

"Ne quid nimis."

THE PUBLIC SCHOOLS SCIENCE MASTERS' ASSOCIATION.

THE annual meeting of this association was held on Jan. 16th at Westminster School, where accommodation had been provided by Dr. Gow. Professor W. A. Tilden, F R.S, president of the association, was in the chair and after referring to the influence which the association had exercised during the past year he went on to say how necessary it was to cultivate the power of seeing. The best instrument for opening the eyes of children was some form or other of natural science. There were other aspects of the question and he was reminded of what was at the present time going on in the University of London. In the medical faculty of that University there was a great struggle going on in regard to the position of chemistry as a subject which was necessary to the education of the medical student. Without going into details an attempt was being made to stifle a large part of the chemistry and to thrust it out of the curriculum. A discussion then arose following a paper read by Mr. R. E. Thwaites (Malvern) upon the possibility of fusing the mathematical and science teaching of public schools. Mr. O. H. Latter (Charterhouse) read a paper upon Nature Study and finally made the following motion:—

> [illegible] to [illegible] of [illegible] ry schools.

This was seconded by Mr. D. Rintoul and carried unanimously. It does not appear from the report with which we have been furnished that any discussion took place as to the chairman's remarks upon what he described as the great struggle with regard to chemistry in the faculty of medicine of the University of London. The majority of his hearers being teachers of pure science would probably have sympathised with his protest against the stifling of a great part of the chemistry of the medical curriculum. But those responsible for the recent changes to which apparently the President of the Public Schools Science Masters' Association objects have insisted that the new regulations do not materially lessen the amount of chemistry learnt by a medical student but provide that it shall be studied more closely in association with the subjects of physiology and pathology. There is a great deal to be said in favour of utilising the study of pure science as a means of preventing the faculty of observation inherent in all children from being crushed out in our preparatory and public schools. Should the efforts of Professor Tilden's association be crowned with success and science be satisfactorily taught to schoolboys intending students of medicine will be amongst those who will profit most from the reform. In the medical curriculum, however, pure science must take a subsidiary position and must be taught in direct relation to strictly professional subjects. Medical students can certainly do with less pure chemistry than has in the past been required from candidates for the medical degrees of the University of London.

THE CERTIFICATION OF LUNATICS.

MEDICAL men are, if we may judge from letters which reach us, often at a loss as to the proper method of dealing with cases of lunacy which occur in their practice. Text-books on insanity do not assist them to any great extent since questions of procedure are usually dealt with by quoting the words of the Lunacy Act, 1890, and the practitioner's difficulty lies not so much in ignorance of the statute as in a quite excusable failure to understand it. The condition which perhaps most frequently gives rise to trouble is that in which on account of mental defect a person becomes unable to pursue his occupation and so to maintain himself and those dependent upon him. Such a person may be a working man who is being attended by his own medical adviser and who has had up to the time of his mental breakdown no relations with the Poor-law except as a contributor to the rates. He is not, therefore, a pauper within the definition of the Lunacy Act as formally given in Section 341, although as a consequence of his incapacity he must become so. In a case of this kind there are several ways of gaining the desired end, that of removal to an asylum, which fall into two groups according as the medical man acts on his own responsibility or communicates with the relieving officer of the district. If the former course is taken the medical man, who is, we are assuming, not a medical officer to a board of guardians, may call the attention of the Commissioners in Lunacy to the case and leave them to act under Section 23. Instead of this he may give information on oath to a "judicial authority" under the Act who will then proceed under Section 13 (2). There is a third method which we mention simply because it has been employed, though its impropriety in the majority of cases is sufficiently obvious. It consists in thrusting the insane person out into the street in order that he may be apprehended by a constable or relieving officer as a lunatic wandering at large under Section 15. If the matter is brought to the notice of the relieving officer that officer may proceed under Section 13 (1), 14 (2), or 20. A consideration here of the proper section to adopt would involve a discussion of sundry subtle points which would expand this note to unwieldy dimensions. We are concerned at the moment merely with the position of the patient's own medical man out of whose hands the management of the case henceforth passes. Whether one medical certificate or two be required he cannot compel the relieving officer to accept one from him. The selection of the certifying medical practitioner is entirely at the discretion of the justice and unless it can be brought to his notice that someone else is especially qualified he will, as a rule, employ the medical officer of the Poor-law institution to which the patient is to be removed. It is often stated by relieving officers that the workhouse medical officer has a "contract" with the guardians to certify pauper lunatics. Guardians, however, have no power to enter into such a contract for the simple reason that the carrying of it out rests with a justice over whom they have no control. On the other hand, it must be noticed that the medical officer of the workhouse is morally entitled to the fee for certifying, since in taking office he has been led to suppose that the justice will not make any departure from the customary procedure without good reason. Any medical man whose patient becomes insane when such patient cannot be dealt with on petition had better reconcile himself to the prospect of getting no further fees from that source.

CENTENARY OF THE ROYAL LONDON OPHTHALMIC HOSPITAL.

"THE light of the body is the eye" is a truth as profound in its physiological significance as in its spiritual interpretation, and whether looked upon as an organ of bodily or intellectual needs or as an index of disease the importance of the eye cannot be overestimated. In the investigations with which ophthalmology is concerned few institutions can take a prior place to that of the Royal Ophthalmic Hospital of London which was founded just 100 years ago and it is impossible to estimate the amount of good which mankind has received from its ministrations. The story of its foundation is an interesting one, for it owes its origin to the sympathies which were aroused in some gentlemen by the terrible sufferings of the men in the navy and army during the early part of the last century who belonged to the force in the Egyptian campaign under Sir Ralph Abercromby. Many of the earliest patients of this hospital were soldiers and sailors invalided home. In this campaign ophthalmia produced great ravages, for out of a regiment of 700 men there were 636 cases of whom 40 became permanently blind in one eye and 50 blind in both. In contrast to this state of affairs we may mention that in the Egyptian campaign of 1882, in consequence of the precautions then taken, though there were 1800 severe cases of ophthalmia after the battle of Tel-el-Kebir not one man lost his sight. Some idea of the amount of suffering relieved by this hospital may be gathered from the statistics for the past year. The number of in-patients relieved was 2122, while the number of new out-patients amounted to 37,987. The total attendances of out-patients were no less than 119,873. Our readers will remember that the original ophthalmic hospital was removed from Charterhouse-square to Moorfields in 1821. This building having been found quite inadequate and unsuitable from sanitary reasons for the work of the institution a new hospital was built in the City-road, London, E.C., the foundation-stone of which was laid by the then Prince of Wales in 1897, the year of the Diamond Jubilee of the late Queen, when he was accompanied by her present Majesty and their daughter Princess Victoria. The ground rent of this new site is £1210 a year and the rates amount to nearly £1000 a year. The latter item has been an incubus upon the management of the hospital since it was opened in 1899. The rates paid for the Moorfields buildings to the City of London were about £55 a year and it is not to the credit of the borough of Finsbury that it insists upon taking from a charity the pecuniary needs of which are great and which renders an incalculable benefit to the many workers in that borough the monstrous sum of £1000 a year. Is it surprising that the hospital should be in debt? One item alone, the liability *to tradesmen*, amounts to over £3000. To meet these heavy demands, and, indeed, to carry on the work of the hospital, the committee was compelled to negotiate a loan of £5000 from the Charity Commissioners by hypothecating a portion of the only endowment of the hospital (a sum of £20,000 then invested in Consols), thus losing the annual interest on that portion of the investment

But even with this assistance and the most careful economy on the part of the committee the past year began with a deficit of £5463, which it is feared will show a considerable increase when the accounts are closed. As we have already said it is impossible to estimate the amount of good this hospital does for mankind. It is not only the poor who come from all parts of the United Kingdom and even from the colonies (sometimes as many as 550 are relieved in one morning) who benefit, but the institution forms a school of ophthalmic science and surgery to which medical practitioners from all parts of the empire come to study. And there is probably not one ophthalmic surgeon of eminence in the United Kingdom or the colonies who has not studied there. The whole empire therefore is indebted to this institution and in common justice the whole empire should contribute towards its support. The King's Hospital Fund for London in its annual report for 1903, referring to the Royal London Ophthalmic Hospital, justly said, "this hospital should receive more support from the public," and this is abundantly clear to anyone who takes the trouble to read the annual reports of the hospital. The annual subscriptions and donations must be increased to £6000 a year if the institution is still to carry on its good work, and in addition to this the sum of £50,000 is required for the rent fund investment the interest of which will pay the rent of the hospital, and £4500 for repayment of the balance of the loan from the Charity Commissioners. Subscriptions should be sent to the secretary, Royal London Ophthalmic Hospital, City-road, E C.

"THE REVELATIONS OF RADIUM."

A VERY interesting lecture under the above title was given by Dr. George B. Batten at a meeting of the Roentgen Society held on Jan. 7th. Dr. Batten commenced by giving a short sketch of the theories of matter that had been held since Newton postulated his projectile theory of light in 1668. Then came Franklin's imponderable fluid theory of electricity in 1748 and next Dalton's atomic theory of matter in 1803. Throughout the nineteenth century the undulatory theory of light and heat associated with the atomic theory of matter was almost universally held. Passing over Clerk Maxwell's view that electricity, light, and heat were identical, Hertz's remarkable experiments in support of this view were mentioned. Hertz demonstrated in 1888 that radiant electricity consisted of large waves in the ether. Next came the announcement of Professor Bose that he had been able to detect electrical waves as small as three millimetres in size. This was followed by Professor Langley announcing the existence of heat rays as large as 70 micro-millimetres, leaving only a gap of about seven octaves in the scale of radiant energy. This gap is now partially filled, it would seem, by M. Blondlot's and Professor Charpentier's "n" rays. In this scale the ordinary red heat rays and all the light rays are in the forty-ninth octave and up to the fifty-first octave chemical or actinic and ultra-violet rays are known to occur. In 1895 Roentgen discovered the x rays which by some are thought to have still smaller wave lengths. Then Sir William Crookes announced the existence of a fourth state of matter and showed that in the vacuum tube the current is carried by material particles of matter in a much smaller state of subdivision than ordinary atoms—"corpuscles, in fact," which form the cathode stream. In still higher vacua the electric current ceases to pass at all, an observation which suggested a difficulty as to accepting the ordinary undulatory ether theory of electricity and light. Possibly the phenomena of radio-activity may help us towards a solution. Becquerel, in 1896, found that the metal uranium has the faculty of spontaneously emitting rays closely analogous to cathode and to Roentgen rays, and Schmidt in 1898 showed that thorium would do the same thing. In the same year M. and Madame Curie succeeded in isolating one decigramme of pure radium from a ton of pitchblende and found that all the radio-active properties of uranium and thorium were intensified in radium at least 500,000 times. On March 16th, 1903, M. Curie announced that pure radium chloride is self-heating. The theory in regard to radio activity is now commonly held to be atomic disintegration and scientific men now speak of elemental decomposition, the pulverisation of atoms into electrons and the reduction of matter into its fourth state. What is undeniable, said Dr. Batten, is that the Daltonian atom has in the century of its acceptance as a fundamental reality suffered destruction. Each of those supposed "ultimates," he added, is now known to be the scene of indescribable activities, a complex piece of mechanism composed of thousands of parts, a star-cluster in miniature subject to all kinds of dynamical vicissitudes, to perturbations, accelerations, internal friction, total or partial disruption. To sum up, the revelations of radium seem to support the corpuscular electron theories of matter and electricity. They open up quite a vista into a new and immense storehouse of energy in the universe, the intra-atomic storehouse beside which the ordinarily available inter-atomic and inter-molecular forces pale into insignificance, if only we can learn to tap that wonderful new source, and this, Dr. Batten confessed, "is the most exciting thing about radium and its congeners."

DESQUAMATION OF THE SKIN IN TYPHOID FEVER.

THOUGH desquamation of the skin in typhoid fever was long ago described by the great French clinician Louis it is either unnoticed or little more than mentioned by most writers. Dreschfeld in Allbutt's "System" says that desquamation of fine branny scales is often observed towards the end of the fever or during convalescence. Osler in the last edition of his book states that branny desquamation is not rare in children and that occasionally the skin peels off in large flakes. The *American Journal of the Medical Sciences* for January contains an important paper by Dr. David Riesman, in which he relates two cases and reviews the literature of the subject. The following is one of his cases. A man was admitted to hospital on Jan. 23rd, 1902, with the eruption of typhoid fever. The attack was severe. The rash became widespread, spots appearing on the face, arms, thighs, and legs. The temperature became normal on Feb. 12th, probably at the end of the fourth week. On March 3rd there was a severe chill, the temperature rose to 106° F., and there was pain in the right side. Pleural effusion followed and aspiration was performed. Early in April the patient left hospital in fair health. Desquamation began during convalescence (date not given). It was widespread and some of the scales were fully a quarter of an inch long. On the chest and abdomen it was most noticeable but it was little less marked on the limbs. It was distinct on the face and neck. On the arms and legs it was in the form of circular bands from one-eighth to one-quarter of an inch thick with intervals of apparently normal skin of the same width. The scalp, shoulders, palms, and soles were not affected. Dr. Riesman concludes that three forms of desquamation in typhoid fever may be distinguished. 1. That confined to the roseolar spots. Sometimes each spot has a tiny vesicle on its summit which forms a thin scale. 2. That appearing as a sequel to sudamina. This form is confined to the area of the sudaminal eruption, though Louis states that the intervening skin may be readily peeled off. The desquamation is usually furfuraceous but is sometimes scaly. It occurs upon the trunk and proximal part of the limbs, never upon the distal are now all back at work and with Dr. Grant we can say that the past is buried.

THE REBUILDING OF ST. BARTHOLOMEW'S HOSPITAL.

THE treasurer of St. Bartholomew's Hospital, Sir Trevor Lawrence, has sent to the press a circular letter reminding readers of the needs of the hospital. He reiterates what we have already said in THE LANCET of Dec. 5th, 1903, p. 1587, and adds that the last occasion on which the hospital appealed for help from the public was 150 years ago. To-day a sum of £500,000 is needed. It is a large sum, but, as we have said many times previously, if the governors at the forthcoming meeting to be held at the Mansion House on Jan. 26th approach the citizens of London and the subjects of this great empire with a practical, thorough, and well-thought-out scheme we are convinced that the money will be forthcoming.

THE medical officer of health of the Cape Colony states that for the week ending Dec. 26th, 1903, only one case of plague was discovered in the colony—namely, a native male at East London on Dec. 23rd. Plague-infected rats were found at Port Elizabeth and at Lady Grey Bridge, but of 415 rats which were examined during the week in the Cape Town and Harbour Board area none was affected with plague. As regards the Mauritius a telegram from the Acting Governor received at the Colonial Office on Jan. 15th states that for the week ending Jan. 14th there were 44 cases of plague and 25 deaths from the disease.

AN appeal emanating from the National Hospital for the Paralysed and Epileptic in Queen-square, London, W.C., has been issued for funds to support an organised system of research into the origin of nervous diseases. The supporters of the appeal have been careful to point out that a separate account of the research department of the hospital will be kept.

MEDICINE AND THE LAW.

The Sale of Food and Drugs Act, 1875.

AT Stratford police-court on Jan. 18th Messrs. Picken Brothers (Limited) were convicted under Section 6 of the Sale of Food and Drugs Act, 1875, and fined £10 with £7 costs for selling cream of tartar found upon analysis to contain lead in the proportion of not less than four grains to the pound. The court was informed that this proportion might have serious results owing to the accumulative effects of lead as a poison and owing to cream of tartar being used by the consumer principally for the making of cooling drinks or in connexion with the making of bread. It was not alleged that the lead had been deliberately added or that the vendors or those who had supplied them were aware of its presence, and it was suggested on behalf of the defendants that it had found its way into the cream of tartar through leaden vessels having been used for the reception of the wine-lees from which the cream of tartar was prepared. A number of technical points were raised by the defence, one of which is of some importance to those whose duty it is to make the analysis and to give the certificate necessary on such occasions. In the case of Messrs. Picken Brothers it was argued that the certificate was defective in not stating the constituent parts of the sample analysed and their proportions but merely that it contained lead in the proportion mentioned above, and that this would be injurious. In the group of cases decided a few years ago with regard to arsenic in beer two certificates were held to be bad. One of these stated that the sample "contained arsenic" and the other that it "contained a serious quantity of arsenic." These cases are reported under Goulder *v.* Rook, 1901, 2 K. B. 290, and in that case an instance was afforded of a certificate of analysis which was held to be sufficient. This one was as follows:—

> I am of opinion that the said sample contained the parts as under of foreign ingredients—viz., arsenious acid to the extent of not less than one eighth of a grain per gallon.

In an earlier case (Fortune *v.* Hanson, 1896, 1 Q. B. 202) a certificate of analysis of milk was held to be bad which stated that the sample "contained the percentage of foreign ingredients as under: 5 per cent. of added water." The distinction to be drawn between an analysis relating to the presence of arsenic in beer and another which determines the presence of added water in milk lies in the fact that arsenic, in however small proportions, is a foreign ingredient in beer but that water is one of the natural constituent parts of milk, and that the point at which it becomes a foreign ingredient is by no means a matter of certainty. In his judgment in Fortune *v.* Hanson Mr. Justice Kennedy put the matter thus, after referring to the form of certificate of analysis to be found in the schedule to the Act: "If something which could not exist as a constituent in water, such as pepper or sand, were found then it would be sufficient to state in the certificate that the sample analysed contained so much per cent. of foreign ingredient; but where the thing said to be added is one of the constituents of the article analysed then, in my opinion, the analyst must in his certificate state the facts on which he has come to his conclusion sufficiently to enable the magistrates to come to a conclusion themselves." The matter is one for the consideration of public analysts, as no one wishes to prosecute unnecessarily inquiries into irrelevant details with regard to the composition of the sample submitted for analysis and possibly to make some slight error in a calculation not material to the case for which his certificate is to be used but likely to be seized on by the defence for the purpose of discrediting the whole of the analysis and certificate. The form of certificate as given in the schedule to the Act is as follows: "I am of opinion that the said sample contained the parts as under, or the percentages of foreign ingredients as under." This is clearly intended to supply alternative forms of certificate for two different classes of case. In the certificate held to be sufficient in Goulder *v.* Rook an attempt appears to have been made to combine the two forms in one.

Illegal Operation by a Herbalist.

A herbalist, named Lardent, and a woman of the name of Ada Booth were convicted before Mr. Justice Ridley at the recent session at the Old Bailey for using an instrument upon a woman named Mitchell with intent to procure a miscarriage. Evidence was given that Mitchell was introduced to the prisoners by a friend and that an attempt was first made to obtain the desired object by the use of drugs. The jury recommended the prisoners to mercy in convicting them, adding an expression of their hope that the woman might be dealt with leniently on account of her state of health. Mr. Justice Ridley, however, did not in the light of the facts proved consider himself justified in making a distinction between them and passed a sentence upon each of five years' penal servitude.

An Object Lesson in the Housing Question.

At an inquest held recently before Mr. Wynne Baxter at Stepney it was proved that the deceased, the wife of a Hebrew teacher, had taken her own life by swallowing poison in despair at the poverty of her circumstances, aggravated by an announcement on the part of the landlord that he was about to raise the rent paid by her and her husband. Apparently the deceased let part of the premises occupied to lodgers when able to do so but had had a difficulty in finding tenants. In commenting upon the rent demanded—25*s.* a week, to be raised to 28*s.*—the coroner observed to a witness, Moss Cohen, the landlord's son, that it was outrageous. He added that it was a case of "cat eat cat" and that such a rent must realise from 40 to 50 per cent. upon the landlord's outlay. The evidence of a policeman was to the effect that the family of the deceased were in distressed circumstances, that her rooms were in a filthy condition, and that her bed was a piece of sacking.

The Hardwicke Society and Antivivisection.

Last week the members of this well known legal debating society discussed the subject of so-called "vivisection." Personal abuse was absent, though neither side lacked conviction or eloquence. Among the speakers were two po- medical qualifications who, avoiding all technicalities, on the advances in medical science which had been about by means of legitimate experiment for the benefit of the human race. *Those holding antivivisection theories made* a strong attack on the demonstration of experiments for the benefit of medical students.

THE UNIVERSITY OF LONDON: THE INSTITUTE OF MEDICAL SCIENCES.

THE following letter has been addressed to the Earl of Rosebery, Chancellor of the University of London:—

MY LORD,—We have observed with satisfaction that the Senate of the University of London have lately issued an appeal for funds to build and endow an Institute of Medical Sciences under the control of the University.

The positions which we severally hold in connexion with the general hospitals of London and their medical schools have *compelled us, especially of late, to give the proposal* that the University should undertake the teaching of the preliminary scientific subjects of the medical curriculum the most serious consideration.

We are convinced that the adoption of the recommendation of the Royal Commission in favour of the concentration of the teaching of these subjects in one or more centres has become a matter of urgent necessity in the interests alike of medical education, of the hospitals, and the medical schools.

We are, My Lord, yours faithfully,
SANDHURST,
Chairman of the Weekly Board, Middlesex Hospital.
TREVOR LAWRENCE,
Treasurer, St. Bartholomew's Hospital.
H. COSMO BONSOR,
Treasurer, Guy's Hospital
SYDNEY HOLLAND,
Chairman, London Hospital.
J. G. WAINWRIGHT,
Treasurer, St. Thomas's Hospital.
TIMOTHY HOLMES,
Treasurer, St. George's Hospital.
H. A. HARBEN,
Chairman, St. Mary's Hospital.
THOS. PERCY BORRETT,
Chairman Charing Cross Hospital.
J. WOLFE-BARRY,
Chairman, Westminster Hospital.

A large sum is required to carry out the scheme. The honorary treasurers of the appeal fund are Dr. J K. Fowler, member of the Senate, and Mr. H. T. Butlin, Dean of the Faculty of Medicine, 35, Clarges-street, W. The following donations in addition to those already announced have been promised to the Institute of Medical Sciences Fund:—

Mr. Alfred Beit	£5000	Sir Henry Roscoe, F.R.S. ...	£100
Messrs. Rothschild and Sons	500	Sir E. Cooper Perry, M.D. Cantab	100
Dr. J. K. Fowler	250	Dr. E Lauriston Shaw... ...	100
Mr. H. J. Chinnery	100	Mr. C. B Lockwood	50
Sir Charles Metcalfe, K C.M.G.	25	Sir R. Douglas Powell, Bart.	50

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on Jan. 14th, Mr. JOHN TWEEDY, the President, being in the chair.

Diplomas of Fellowship were issued to two candidates who have now attained the age of 25 years.

A report from the museum committee was submitted. The report mentioned *inter alia* the addition to the museum of a number of interesting specimens illustrating the agreement of external sexual characters in sheep and fowls, the results of experiments performed by Mr. S G. Shattock and Dr. C. G. Seligmann.

The best thanks of the Council were given to Dr. G. V. Poore for presenting from the library of the late Mr. Marcus Beck notes of Mr. John Marshall's lectures on surgery at University College [illegible]

In[illegible] *renewing the exist*[illegible] th[illegible] Asylums Board for [illegible] was postponed for further consideration.

The Council considered some further information supplied to it by the Director-General of the Army Medical Service on the subject of the physical disability of recruits and it was decided to reply to the Physical Deterioration Committee that it saw no ground to modify the opinion which it had previously expressed on the matter.

Sir HENRY G. HOWSE, as chairman of the committee on the physical disability of recruits for the army, reported that a letter had been received from the Physical Deterioration *Committee asking the College to recommend the names* of two surgeons who would give evidence representing the views of the profession in general on the condition of the eyes and the prevalence of syphilis respectively among the poorer classes of the population, and that the names of Mr. Tweedy, the President, and Sir Alfred Cooper, Vice-President, had been submitted to the committee. The nomination of these two gentlemen was approved.

The SECRETARY reported the receipt of essays for the Jacksonian and Triennial prizes.

Mr. Tweedy, the President, was appointed Hunterian Orator *for 1905*

The President presented to the College an enamelled gold presidential badge representing the College seal. A unanimous vote of thanks was given to him for his gift.

The SECRETARY reported that the portrait of Sir Spencer Wells had been returned from Nottingham and that a letter had been received from the director of the Nottingham Museum and Art Gallery conveying the thanks of the Art Museum committee of the city corporation for the loan of the portrait.

On the recommendation of the examiners of Part I. of the examination *in* public health the *Council* adopted the following resolutions:—

(*a*) That in the interest of factory and workshop workers the amount of carbonic acid in the air of such places should not exceed nine volumes in 10,000. (*b*) That carbonic acid produced by the combustion of gas or oil used for lighting purposes should be made to pass directly to the outside air and should not be allowed to contaminate the air of the factory or workshop.

It was resolved that copies of these resolutions should be forwarded to the Secretary of State for the Home Department and to the Incorporated Society of Medical Officers of Health.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8668 births and 5557 *deaths* were registered during the week ending Jan. 16th. The annual rate of mortality in these towns, which had been 15·4, 20 6, and 20·3 per 1000 in the three preceding weeks, further *declined* last week to 19·0 per 1000. In London the death rate was 18 8 per 1000, while it averaged 19·1 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 8 5 in Coventry, 9 6 in Hornsey, 10·3 in [illegible] 10 8 in Leyton, 11·1 in Devonport, 12·2 in [illegible] rton, and 12·6 in Derby; while [illegible] Gateshead, 25 6 in Rochdale, [illegible] Warrington, 29 0 in Preston, 30·1 in West Hartlepool, 33 0 in Merthyr Tydfil, and 38 2 in Wigan. The 5557 deaths in these towns last week included 450 which were referred to the principal infectious diseases, against 389, 495, and 462 in the three preceding weeks; of these 450 deaths 136 resulted from measles, 131 from whooping-cough, 62 from diarrhœa, 51 from diphtheria, 44 from scarlet fever, 24 from "fever" (principally enteric), and two from small-pox. No death from any of these principal infectious diseases was registered last week in Hornsey, Hastings, Brighton, Devonport, Burton-on-Trent, Coventry, Derby, Bootle, Barrow-in Furness, or Huddersfield; among the other towns the highest death-rates from these diseases were recorded in Walthamstow, [illegible] Salford, Preston, and Handsworth [illegible] ity from measles Gateshead. [illegible] m, Warrington, occurred in [illegible] Salford, Preston Rotherham, and Sunderland; from scarlet fever in Merthyr Tydfil; from whooping-cough in Portsmouth, Handsworth, Birkenhead, Wigan, West Hartlepool, Gateshead, and Newport (Mon.); and from diarrhœa in Walthamstow. One fatal case of *small-pox* was registered last week in Nottingham and one in Sunderland, but not one in any other of the 76 large towns. The number of small-pox patients in the Metropolitan Asylums hospitals, which had been 26 on each of the two preceding Saturdays, was again 26 on Saturday last, Jan. 16th; four new cases were admitted during the week, against seven, four, and six in the three preceding weeks. The number of scarlet fever patients remaining under treatment in these hospitals and in the London Fever Hospital was 1660 at the end of last week, against 1617, 1632, and 1659 at the end of the three preceding weeks; 195 new cases were admitted during the week, against 142, 194, and 201 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 271, 404, and 433 in the three preceding weeks, declined again last week to 406, but were 96 in excess of the number in the corresponding period of last year. The causes of 71, or 1·3 per cent., of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Bradford, Newcastle-on-Tyne, and in 46 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, St. Helens, Warrington, Blackburn, Sheffield, Sunderland, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 20·8, 21·7, and 23·2 per 1000 in the three preceding weeks, declined again to 20·2 per 1000 during the week ending Jan. 16th, but was 1·2 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 16 8 in Edinburgh and 18·1 in Leith, to 24·3 in Dundee and 27·7 in Perth. The 668 deaths in these towns included 23 which were referred to measles, 15 to whooping-cough, 13 to diarrhœa, five to small-pox, three to diphtheria, three to "fever," and one to scarlet fever. In all 63 deaths resulted from these principal infectious diseases last week, against 73, 71, and 53 in the three preceding weeks. These 63 deaths were equal to an annual rate of 1·9 per 1000, which was 0·4 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been 25, 26, and 13 in the three preceding weeks, rose again last week to 23, of which 19 occurred in Glasgow and two in Paisley. The deaths from whooping-cough, which had been 16, 14, and 15 in the three preceding weeks, were again 15 last week, and included six in Aberdeen, two in Glasgow, two in Edinburgh, two in Dundee, and two in Leith. The fatal cases of diarrhœa, which had been 16, 21, and 15 in the three preceding weeks, further declined last week to 13, of which six were registered in Edinburgh, four in Glasgow, and two in Dundee. The deaths from small-pox, which had been four, five, and three in the three preceding weeks, rose again to five last week, and included four in Glasgow and one in Leith. Of the three fatal cases of diphtheria two were recorded in Paisley. The three deaths from "fever" included two in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 180, 177, and 213 in the three preceding weeks, declined again last week to 198, but were 24 in excess of the number in the corresponding period of last year. The causes of 21, or more than 3 per cent, of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 19 9, 31·8, and 27·8 per 1000 in the three preceding weeks, rose again to 28·8 per 1000 during the week ending Jan. 16th. During the past four weeks the death-rate has averaged 27 1 per 1000, the rates during the same period being 18 2 in London and 18 4 in Edinburgh. The 209 deaths belonging to Dublin, registered during the week under notice, were seven in excess of the number in the preceding week, and included ten which were referred to the principal infectious diseases, against seven, 16, and 23 in the three preceding weeks; of these, five resulted from whooping-cough, three from diarrhœa, and two from "fever," but not one from any other of the principal infectious diseases. These ten deaths were equal to an annual rate of 1·4 per 1000, the death-rates last week from the principal infectious diseases being 1·5 in London and 1·4 in Edinburgh. The fatal cases of whooping cough, which had been three, 12, and nine in the three preceding weeks, further declined last week to five. The deaths referred to different forms of "fever," which had been two, two, and five in the three preceding weeks, declined again to two last week. The three fatal cases of diarrhœa corresponded with the number in the preceding week. The 209 deaths in Dublin last week included 31 of children under one year of age and 61 of persons aged 60 years and upwards; the deaths of infants showed a slight decline, while those of elderly persons were in excess of the number in the preceding week. Four inquest cases and four deaths from violence were registered, and 82, or nearly two-fifths, of the deaths occurred in public institutions. The causes of nine, or more than 4 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Civil Practitioner J. D. Wynne to be Surgeon and Agent at Clonmel (dated Jan. 18th, 1904).

ROYAL ARMY MEDICAL CORPS.

Lieutenant Colonel J. Hickman retires on retired pay (dated Jan. 20th, 1904); Captain J. M. Buist, from the Seconded List, to be Captain (dated Dec. 1st, 1903).

Captain J. M. Buist is instructed to proceed to Woolwich, for duty. Major A. L. Borradaile is to join the Western District for duty. Captain E. S. Clark, lately at the Royal Army Medical College, is to join the Home District for duty Captain A. C. Lupton and Captain J. C. B. Statham are selected to attend a course of study at the Royal Army Medical College in London. Lieutenant-Colonel W. G. Macpherson, C.M.G., is appointed Principal Medical Officer, North China.

VOLUNTEER CORPS.

Rifle: 2nd Volunteer Battalion the East Lancashire Regiment: Richard Langford Fitz-Gerald to be Surgeon-Lieutenant (dated Jan. 16th, 1904). 2nd Volunteer Battalion the Sherwood Foresters (Nottinghamshire and Derbyshire Regiment): Surgeon-Lieutenant-Colonel J. Knox resigns his commission with permission to retain his rank and to wear the prescribed uniform (dated Jan. 16th, 1904). 2nd Volunteer Battalion the Manchester Regiment: Surgeon-Major G. H. Darwin resigns his commission (dated Jan. 16th, 1904).

THE TRAINING OF BOYS FOR SEA SERVICE.

On Jan. 14th, at the Royal United Service Institution, Admiral Sir J. C. Dalrymple Hay, in a lecture on the above subject, said that the Royal Navy at present employed about 83,000 seamen who had entered as boys in the training ships. To meet losses by the discharge of seamen at the age limit and by death 4700 boys were annually entered for the naval training ships and about 1000 in His Majesty's ship *Northampton* and her tenders. There were now 9900 boys borne for training. The number of 83,000 seamen was sufficient for the peace force now in commission but if war should break out the Naval Reserve was the only trained force on which we could rely. The Naval Reserve was a very trustworthy force and its strength up to the end of last year was 26,031. It must be remembered that these men being taken from the merchant service in time of war would deprive it of its best men at the very time that our mercantile marine would be fully employed in provisioning this country and in distributing its commerce. A further Naval Reserve was being created which was to number 15 000 men and which would apparently require an additional number of entries of boys. The sea service required, like every other trade and profession, a long apprenticeship and it was proved that after the age of 17 years lads were not attracted by its adventurous character. An entry of 4700 boys annually was sufficient to keep up the number of seamen for the Royal Navy. It was obvious, therefore, that a further entry of 9500 boys would supply the 175 000 men required for the mercantile marine. He thought that the State should step in and do for the merchant navy what it had already done for the Royal Navy. Was it too much to hope that the Admiralty and the Board of Trade could arrange for such an increase of training and make the men of the merchant navy all subjects of the King and a real reserve for the navy in case of war?

The War Office is asking for certified returns from all officers of the Royal Army Medical Corps whose war services are not correctly recorded in the quarterly "Army List."

Correspondence.

"Audi alteram partem."

THE PROPOSAL TO PROHIBIT MEDICAL PRACTITIONERS FROM DISPENSING.

To the Editors of The Lancet.

Sirs,—I observe that on Jan. 27th the members of a branch of the British Medical Association are to be asked to pass a motion to the effect that "no person registered under the Medical Act (with a few exceptions) shall dispense or supply drugs or other medicaments to anyone." The suggested penalty for a first offence against the aforesaid is to be a fine of not less than £100 and for the second offence erasure peremptorily from the Medical Register. The General Medical Council has judiciary power, of course, over the medical practitioner but it exercises no jurisdiction and is never likely to have any legal authority over the druggist. Those who, like myself, are engaged in consulting practice know well the unlimited extent to which one's prescriptions may be bandied about and that the druggist may without let or hindrance dispense any given prescription as frequently as its repetition is requested. It is now suggested that practically all practitioners—not only without option but under heavy penalty—should be compelled to adopt this method of treating and of interchange with their patients, but I fear the possible undesirable effects of such an enactment have not been duly considered by those who are responsible for the promulgation of this proposed scheme' Take the practitioners in populous but not over-wealthy districts and we are bound to infer that: if this project be adopted many of their patients will be not only unwilling but unable to pay both for the prescription and for the medicaments which may be written thereon, for the patient's ailment will in such circumstances be required to contribute towards the maintenance of two expensive establishments, that of the medical man and that of the druggist, instead of one as at present. The ever-increasing demand upon the out patient departments of our hospitals is already a vexed question and one difficult to cope with, but it will be apparent to everyone that if the scheme which I now refer to should eventually become law our out patient departments will become still more unwieldy and more reprehensible, for the new procedure will prove too expensive to many and will drive to our hospitals those who, but for this new requirement and unnecessary extra expense, would never have entertained the idea of seeking advice at any of our charitable institutions. I feel assured, therefore, that this departure is one which cannot commend itself to the medical profession generally and should be strenuously opposed whilst the project is still in its embryonic state.

I am, Sirs, yours faithfully,

Gordon square, W.C., Jan. 19th, 1904. James Oliver.

MALIGNANT GROWTHS AND NORMAL REPRODUCTIVE TISSUES.

To the Editors of The Lancet.

Sirs,—In your issue of Dec. 26th, 1903, p. 1830, there is an abstract of some observations by Professor J. B. Farmer, Mr. J. E. S. Moore, and Mr. C. E. Walker. They have been investigating karyokinetic processes in malignant tumours, a field of investigation in which I, too, worked extensively some years ago. Since my observations do not seem to be familiar to these authors, who are, I believe, botanists by profession, I should be glad if you would give me space in your journal for the following remarks. These authors have found that in the
tumours the mitotic figures
. reductive
of sexual
thors state
ic, in fact,
ir chromo-
are also changed in shape. These observations coincide more or less with those described some time ago in various publications—e.g., Virchow's Archiv, vol. cxix., 1890, p. 299; *Archiv fur Mikroskopische Anatomie*, vol. xliii.; the *Festschrift fur Virchow*, in 1891; and in the *Verhandlungen der Anatomischen Gesellschaft*, in 1891, p. 255, and elsewhere. I have given a connected account of these processes in my monograph, entitled "Die Studien über die Spezifizität, den Altruismus und die Anaplasie der Zellen" (Berlin, 1893), and reverted to the subject in my book on "Die Mikroskopische Diagnose der Bösartigen Geschwülste" (second edition, Berlin, 1902) on pp. 91 *et seq.*

According to my investigations it is not a question of a reduction to exactly one-half the normal number of chromosomes nor does the reductive division occur in the manner seen in the maturation of ova and spermatozoa. According to my observations the reduction is effected in a two-fold manner—either by asymmetrical nuclear division or by a destruction of individual chromosomes without destruction of all the nuclear substance. The first result by either of these two processes is cells with a smaller number of chromosomes than normal. I have called these cells *hypochromatic.* In the further stages of development these chromosomes may be doubled, quadrupled, sextupled, and so on, so that from hypochromatic hyperchromatic cells may arise but always with a smaller than the normal number of chromosomes of human cells. I have sought to correlate with these observations the peculiar characters which the cells of malignant growths possess, especially their greater power of independent existence and their loss of differentiation as compared with the normal tissue cells. The combination of these two properties I have termed *anaplasia,* an expression now very generally employed in the scientific world even by those investigators who do not altogether agree with the details of my observations on the cell processes. I have also given a detailed account of the change of form of the chromosomes and have shown how extraordinarily manifold their form may be in malignant tumours which in nearly all cases differ not only from normal tissues but also amongst each other, so that not only in different cancers but in one and the same the most varied forms of chromosomes may be found.

Since these investigations are, perhaps, but little known in England I am naturally anxious in reference to the investigations of Professor Farmer, Mr. Moore, and Mr. Walker to guard my priority of observations in this field.

I am, Sirs, yours faithfully,

Berlin, Jan. 16th, 1904 Professor D. v. Hansemann.

To the Editors of The Lancet.

Sirs,—The letter of Professor v. Hansemann, a proof of which you have allowed us to see, contains a number of misleading statements some of which call for comment. Incidentally we may remark that only one of us is a botanist, although two of us have been frequently associated in work on vegetable, as well as on animal, cytology.

We are at a loss to understand why Professor v. Hansemann should assume that we are unaware of his investigations. As a matter of fact we are perfectly familiar with them, and as a consequence with the circumstance that our own conclusions respecting the meaning of the cytological phenomena in question are in all essential features at variance with those arrived at by him. It is perfectly clear both from his letter and still more so from a study of his work of 1902, cited by him, that he has either entirely misapprehended the facts connected with the "reducing" divisions characteristic of sexually reproductive tissue or that he has not succeeded in tracing the similarity that exists between the processes in them and in malignant growths respectively

Professor v. Hansemann's statement that the occurrence of an odd number of chromosomes in any cell of any animal is necessarily due to either an asymmetrical division or to degeneration (or elimination) is not in accordance with known facts. There is no *a priori* reason why a cell that has undergone reduction should not possess an odd number of chromosomes, and, indeed, some animals *do* exhibit such numbers. It is only the *somatic* cells that normally must contain an even number and this is due to the fact that ovum and sperm each possess identical (even or odd) numbers before their union in fertilisation.

No one who has examined the dividing nuclei of malignant tissue has doubted the occurrence of abnormalities, but no one, so far as we are aware, and certainly not Professor v. Hansemann, had previously suggested those resemblances between reproductive and malignant tissues that are involved in the recognition, in each, of the existence of the heterotype mitosis. Indeed, we have so far failed to identify those special points in our own communication for the discovery of which Professor v. Hansemann is so anxious to guard his priority. For whilst, in common with others who have worked at this subject, we have naturally recognised the frequent occurrences of irregular nuclear divisions, the conclusions we have reached, as well as the interpretation we have put on the facts, are, as Professor v. Hansemann admits in his letter, widely divergent from those to which he has himself been led.

We are, Sirs, yours faithfully,
J. BRETLAND FARMER.
J. E S. MOORE.
CHARLES WALKER.

⁂ In the circumstances we decided to give Professor Farmer, Mr. Moore, and Mr. Walker an opportunity of replying to Professor v. Hansemann in the same issue of THE LANCET in which Professor v. Hansemann's letter appears.—ED. L.

THE METROPOLITAN ASYLUMS BOARD AND ITS ASSISTANT MEDICAL OFFICERS.

To the Editors of THE LANCET.

SIRS,—To the reasons assigned by you in the annotation on the above subject in THE LANCET of Jan. 16th, p. 177, for a more reasonable notice than one month being given prior to the dismissal of the seven assistant medical officers on the ground that there is no work for them to do, may I add a further consideration—to wit, the probability that the services of these gentlemen will be required should the Local Government Board authorise the managers of the Asylums Board to provide accommodation for the isolation and treatment of persons suffering from consumption? In this connexion I would point out that the Poor-law infirmaries are rapidly filling up, pauperism already standing at a high level, and being likely still further to increase should the winter prove severe. In which event it would be of great advantage to the metropolis should the Local Government Board's decision enable the managers to relieve those establishments by the transfer to Gore Farm hospitals of a sufficient number of consumptives—say 850—to fill the lower hospital which was designed for the reception of that number of small-pox patients.

I am, Sirs, yours faithfully,
Kensington, Jan. 16th, 1904. T. ORME DUDFIELD.

⁂ We publish Dr. Dadfield's sensible suggestion with pleasure and wonder whether it is too late for the Metropolitan Asylums Board to reconsider its injudicious action. The medical profession would like to hear the reasons for the dismissal of the seven assistant medical officers fully explained. Is it true that the places of the salaried men are to be taken by unpaid young men seeking to acquire the instruction necessary to obtain the diploma of public health? We have heard that this dangerous innovation may be going to take place.—ED. L.

THE UNRESTRICTED SALE OF DANGEROUS DRUGS.

To the Editors of THE LANCET.

SIRS,—I desire to call attention to a grave defect in the law controlling the sale of dangerous drugs. There is apparently nothing to prevent any person who obtains possession of a prescription from procuring by its aid enough poison to kill a community.

An undated copy of a prescription has just come into my possession from a firm of pharmaceutical chemists by means of which a patient in a short period of time had obtained no less than 17½ ounces of a 20 per cent. solution of cocaine hydrochlorate. This quantity of solution contains 1680 grains of the highly poisonous alkaloid, of which, according to the British Pharmacopœia, the maximum dose is half a grain. This large amount of poison had been procured by taking this copy of a prescription to one firm of druggists after another (the names of many different firms are stamped upon it) and obtaining an ounce at a time from each, save on one occasion when half an ounce only was supplied. Half an ounce only was ordered on the prescription. With the exception of the making up of a double dose everything seems to have been done to meet the requirements of the law. The original prescription had been apparently given to the patient by a high authority. But anything more serious to the welfare of the public cannot well be imagined than a system under which drug habits go unchecked and deadly poisons can be procured wholesale. Druggists cannot well hesitate to make up the prescriptions of well-known medical men, especially when a prescription bears upon its face the stamped names of some of the best firms in the trade certifying that it has already been dispensed by them.

The remedy which suggests itself to me and which probably might be adopted not only in connexion with the prescribing of lethal doses of dangerous drugs but also with regard to many prescriptions for disorders requiring but a short course of treatment, is one which I am assured by a highly respectable firm of pharmaceutical chemists they would gladly welcome. It is, that in all cases where medical men prescribe such drugs as morphia, opium, cocaine, &c., which are known to induce a habit, the words "*Not to be repeated*" should be written across the prescription, which should be signed by the prescriber in full and not merely initialled. By this means the prescriber would be able to control the quantity of the drug taken or used and prescriptions would not be handed about from one person to another *ad libitum*, especially if the words "*not transferable*" were added. We know but too well how many valuable lives are lost and reputations ruined under the working of the present system which loudly calls for amendment. I may add that I fortunately obtained possession of the poison and the prescription from the patient and was thus enabled to save a valuable life.

I am, Sirs, yours faithfully,
Margaret-street, W., Jan. 19th, 1904. T. OUTTERSON WOOD.

SOME FORMS OF CHRONIC ABDOMINAL SURGICAL DISEASE.

To the Editors of THE LANCET.

SIRS,—Mr. E. Stanmore Bishop in his address under this title[1] gives currency to two theories concerning the action of the colon which I believe to be ill-founded. The first of these is Dr. R. W. Leftwich's theory (to quote Mr. Bishop's words) "that the contents of the large intestine are carried forwards mainly by syphonage, although peristaltic action is also present to a subsidiary extent." The objections to this theory are: 1. It assumes that the walls of the colon have a sufficient rigidity to allow syphonage to occur; not only is the wall of the *living* colon eminently collapsable but it is subject to the intra-abdominal tension kept up constantly by the elasticity and contraction of the abdominal walls. 2. It assumes that the contents of the descending colon are in a sufficiently fluid condition, which is not normally the case. 3. Dr. W. B. Cannon's[2] observations on the passage of the contents of the colon made on the cat by means of bismuth laden food and x rays, revealed the fact that there is normally an antiperistalsis in the proximal part of the colon; in this movement the parts corresponding to the human ascending and transverse colon were involved. In the arrangements of its muscular coat the colon of the cat does not differ from that of man; we may safely infer that the peristaltic movements are the same. The characteristic arrangement of the muscular coats of the colon is adaptational to the peculiar peristaltic movements which occur in the colon. 4. The muscular coats of a foot of colon weigh more than those of two feet of small intestine. One may infer that they are sufficient for their work in the case of the great intestine as in the case of the small without the aid of syphonage. 5. Except in the possession of an extremely short mesentery for the ascending colon, the arrangement of the great intestine of man does not differ from that seen in many mammals, in which, because of their posture, syphonage is impossible. Yet the muscular coats of the human colon are better developed than is generally the case in mammals. 6. It is impossible to obtain a syphon action in the human colon by experiment on the cadaver.

---

[1] THE LANCET, Jan. 16th, 1904, p. 139.
[2] American Journal of Physiology, vol. vi., p. 251.

The second theory, to which I think strong objection should be made, is that of the nature of the great intestine, which Mr. Stanmore Bishop regards as "the slopstone and drain" to carry off the refuse of the stomach and small intestine. It is not nature's habit to use seven or eight feet of an elaborate tube furnished with a carpet of glands and lymphoid tissue, supplied most richly with arteries, veins, and lymphatics, with a delicate and easily disorganised nervous mechanism, to play the part of an excretory duct or cloaca. Yet Metchnikoff[3] and Dr. E. Barclay-Smith[4] have each concluded that the great intestine, as far as man is concerned, is a useless and dangerous structure and that its presence in man is a blunder on the part of nature which, however, can be obviated by the aid of the surgeon. The Metchnikoffian theory of the great intestine rests on two facts: (1) we do not know the function of the great intestine; and (2) the health of the body is improved by the removal of a *diseased* great intestine. There is no evidence that the excision of a healthy or normal great intestine leads to an improvement of the well being of the individual.

My reason for protesting against the "syphon drain-pipe" theory of the great intestine is that, were it accepted by a younger generation, it would retard a much-needed inquiry into the functions of the colon and the normal stimuli whereby its nervous and muscular mechanisms are set in operation

From the point of view of the comparative anatomist it seems a more logical inference to suppose that it would be easier, did we know the functions of the several segments of the alimentary canal, to adapt the human diet to the canal than by surgical interference to modify the canal to suit the artificial diet of civilisation.

I am, Sirs, yours faithfully,
A. KEITH, M.D. Aberd.
London Hospital Medical School, Jan. 18th, 1904.

THE BORDERLANDS OF INFECTIOUS DISEASES AND THEIR MANAGEMENT.

To the Editors of THE LANCET.

SIRS,—We seem to be on the verge of obtaining the clear white light of truth on the second part of this subject, thanks to the manly courage of Dr. H. E. J. Biss in revealing some of the facts. The question of the borderlands of infectious diseases is eclipsed for the moment by the facts disclosed as to the critical state of the Metropolitan Asylums Board's hospitals and, as a matter of fact, by many medical officers of health as to isolation hospitals generally, as well as notably by Mr. E. D Marriott of Nottingham.

The facts divulged from time to time for some years past have caused some misgiving to many, but no one outside an isolation hospital could credit that they were as serious as stated by Dr. Biss in his last letter. If during five years in the Metropolitan Asylums Board's hospitals 2562 patients who had been [illegible] ted with diphtheria [illegible] if about the same [illegible] tal suffering from [illegible] fever then I think the strongest case is made out for an immediate inquiry so that the medical staffs of these hospitals may have an [illegible] at least, some of these miscalled isolation hospitals.

If the results made known are only obtainable after isolation hospitals are constructed *secundum artem*, and under efficient management, then there is only one course open—the doors must be closed. But I am still loth to believe that they cannot be rendered serviceable for their purpose, notwithstanding Dr. Biss's alarming figures. I therefore join in calling upon those who are answerable for the construction and management of these hospitals to institute a public inquiry by a competent and disinterested commission without delay. Should those in authority burke an inquiry it will become a question of "urgent public importance" in the House of Commons. Meanwhile I would go further and say, ought not the construction of new isolation hospitals to be prohibited pending an inquiry?

I am, Sirs, yours faithfully,
Rugby, Jan. 16th, 1904. CLEMENT DUKES.

CHLORETONE IN SEA-SICKNESS.

To the Editors of THE LANCET.

SIRS,—As it was through the correspondence columns of your valued journal that I was first made acquainted with the efficacy of chloretone in sea-sickness, and as I have just recently realised the value of that information, I deem it my duty to contribute through the same medium my grateful testimony in confirmation of your correspondents' reports. My daughter (aged about 20 years) is so fond of the sea that she always prefers boat to train, notwithstanding the fact that she has (until this last trip) invariably had to undergo the ordeal of at least 24 hours' sea-sickness. She sailed from London Docks on Dec. 30th per s.s. *Avon* to Grangemouth and returned by same steamer last Friday morning. On this occasion she took with her a supply of chloretone capsules, five grains each, and for the first time in her life made the sea trip not only without sickness but with improved appetite and spirits. In fact, she partook with relish of fats and vegetables, things that she could not tolerate at home. She attributes (I believe rightly) her immunity to the chloretone capsules, two of which she took before setting out and returning. She was directed to take one every two hours if threatened with sickness, but fortunately occasion did not arise, although the trip both ways was very rough, the vessel shipping numerous heavy seas and rolling very much. I may also add that I have found the same preparation useful in some cases of insomnia, reflex headache and vomiting, and would very much like if some of your numerous readers could favour *THE LANCET* with their experience of its effects in these directions and such explanation of its action as may assist in indicating suitable cases and mode of administration.

Apologising for the unintended length of this communication, I am, Sirs, yours faithfully,
JOHN DUNLOP, L.R.C.P. Edin., &c.
Seven Kings, Ilford, Jan. 14th, 1904.

THE LUNG REFLEX OF ABRAMS.

To the Editors of THE LANCET.

SIRS,—I am again obliged to correct Dr. Campbell's statement to the effect that I acknowledge the action of the respiratory muscles "in explaining reflex pulmonary expansion." Yes; after the expansion has passed a certain point, already frequently pointed out, and safeguarded in my last letter by the words "after passive recoil of the chest has done its part." I am afraid I must admit my inability to follow Dr. Campbell in his comparison of the action of an entire organ, like the heart, with that of a group of muscles only forming part of a complicated system of machinery, nor shall I venture to entertain the somewhat mystical conception that muscles when relaxing may be at the same time contracting, more especially as this is based on observations which Dr. Campbell has made upon himself.

Now in respect of lung contraction in a limited area Dr. Campbell *dismisses* physiological experiments as valueless, believing, curiously enough, that in such the lungs are necessarily subjected to a positive pressure. By no means. I intended to refer more particularly to portions of lung inclosed in the plethysmograph from which the air had been exhausted. If, as Dr. Campbell fancies, the effect of bronchiolar constriction is to drive the contained air backwards into the alveoli, how is it that the manometer records an increase of pressure? The vagus acts chiefly on the smallest bronchioles and what may be termed the air wave in lung contraction travels from within outwards. If, on the other hand, the air were driven inwards, not only would there be no rise of pressure but the total lung volume would remain constant for the time being. As the reverse of both these conditions occurs the hypothesis of an alveolar inflation is insusceptible of serious consideration. Even clinical observation proves that sudden obstruction of a bronchus causes collapse of the pertaining lung territory. Finally, the question is put, Could a vagus stimulation produce a pulmonary contraction sufficient to cause a darkening (i.e., diminished brightness) in the fluoroscopic field and a dulling of the percussion note?

---

[3] The Nature of Man. English translation, by P. C. Mitchell. London, 1903.

[4] Proceedings of the Cambridge Philosophical Society, vol. xii., Part I., 1903.

I answer, certainly. In the latter case it is only necessary to recall the fact that in the normal lung the percussion note at the end of expiration is less resonant than that yielded at the end of inspiration.

I am, Sirs, yours faithfully,

Henrietta-street, W., Jan. 15th, 1904. A. G. Auld.

*** In closing this correspondence last week we offered Dr. Auld an opportunity of reply of which by an oversight he did not avail himself. This correspondence must now cease.—Ed. L.

PROFESSIONAL ETHICS.

To the Editors of The Lancet.

Sirs,—I inclose the facts of a recent incident that occurred in my practice in the hope that you will publish them, with comments, if you think it desirable. I can vouch for the truth of every word of the statement and can only add that in my judgment many offences "infamous in a professional sense" are paltry compared with this exhibition of greed and lack of professional honour.

I am, Sirs, yours faithfully,

Jan. 10th, 1904. F.R C.S.

PS.—I inclose my card.

[Inclosure.]

A patient, living about 20 miles from London, was recently found by his medical adviser to be suffering from prostatic calculus a uric acid stone having become impacted in the prostatic urethra. Efforts were first made, as the stone was not supposed to be large, to dissolve it sufficiently to pass per urethram. These efforts failing it was decided to consult a London specialist, and accordingly the practitioner wrote a careful history of the case to the selected man and arranged an appointment. The specialist confirmed the diagnosis, alleging great danger in delay, telling him that his doctor had acted wrongly in his treatment and urging him immediately to submit himself to operation.

It was ultimately settled that he should go into a public hospital, to which the specialist was attached, on the following day in order that it might be done. In consideration of this the patient—with a considerable family, and living in a house of about £35 per annum rental value—was induced to promise to send that same night to the specialist a fee of 20 guineas *over and above the two-guinea* consulting fee. But he was carefully enjoined not to tell his doctor or anyone else of this transaction. He returned home that afternoon, calling upon his medical adviser on the way with a message from the "consultant" that he was too busy to write anything about the case, and stating that there was a "great big stone" which ought never to have been left so long.

Early the following morning he sent an urgent message to his doctor to the effect that he could not pass his water and on the doctor's arrival the stone had been happily passed; it was of the shape of a small sparrow's egg and measured five-eighths of an inch in length and one inch in girth at its middle—that is to say, its largest transverse diameter was about one-twenty-fourth of an inch more than that of a No. 12 catheter; it weighed 14 grains nearly when dry and showed ample appearance of superficial disintegration as a result of the efforts to dissolve it. The necessity for the operation having passed the patient began to feel anxious about his 20 guineas which he had duly sent off the previous night and only on that account did he divulge the fact of the payment.

It is well to be able to record that he got it back, but the medical practitioner did not receive a single word of advice or any report of the case from the consultant whom he had approached for help and guidance. The patient, however, received a letter returning his cheque and containing instructions to the effect that should any bleeding or dysuria occur he had better go up to the specialist at once!

LONDON HOSPITALS AND CENTRAL CONTROL.

To the Editors of The Lancet.

Sirs,—In the letter which you have already done me the favour to publish upon this subject I did not get beyond the position that some central control of hospitals would almost certainly be advantageous; and I will now, with your permission, approach the manner in which such control might be obtained. The letter of Dr. Lauriston E. Shaw in your issue of Jan. 16th, p. 186, and letters which have appeared in the *Times* from the original writer upon the question, from the Hon. Sydney Holland, and from Mr. Loch, are all of them valuable contributions to the formation of a sound judgment upon a very important but very difficult and complicated problem, and proceed from writers whose opinions are entitled to consideration and respect.

Among these writers there seems to be a general agreement that a useful board of control might be formed by some process of election or nomination from the committees of the great collecting funds and from the governing authorities of the hospitals themselves. Dissent from such a view, resting upon such authority, can only be expressed with diffidence, but the medical profession ha now had experience for nearly 50 years of a body constitute in an analogous manner, and the experience cannot b described as encouraging. The General Medical Council i partly composed of members appointed by corporations th proceedings of which it was collectively intended to control and partly of members nominated by the Crown or electe by the profession. The corporation members have certainl been expected, in addition to their duties on the Council, t take care of the interests of the bodies appointing them and in this respect they have occupied positions fairl analogous to those which the representatives of hospital would occupy on the suggested board. The Crown and th elected members have been looked upon somewhat in th light of watchdogs over their colleagues, and have occupie positions fairly analogous to those which the member appointed by the collecting funds would occupy on th suggested board. The efforts of hospital representative would be primarily directed towards the attainment of th maximum of independence for their several institution and towards combination when this independence ap peared to them to be in danger; while the efforts of th representatives of the funds would be mainly directed t wards the attainment of the largest possible measure of co trol. The inevitable result would be a deadlock. The Gener Medical Council, in the 48 years of its existence, has not y been able to secure the proper preliminary education o medical students; and has lately been so evenly divided upo a crucial question that an appeal to the casting vote of th President was only avoided by the departure of one of th members from the meeting room. The members of th Council are not to blame. There are too many of them, the powers are inadequate to the proper performance of the supposed duties, and some of them are compelled to conside the apparent interests of the corporations which they a collectively intended to control. The proposed hospita board would, in my humble judgment, break down in precisely similar manner, even apart from the consideratio that the election of members by the funds would afford n security that the gentlemen (or ladies) elected had any rea knowledge of hospital management or any competence t decide the questions which would be submitted to them The board would, in my opinion, possess too much of a amateur character, it would of necessity be far too numero it would have no continuity of policy, and it would break i pieces under the stress of internal dissension.

It has been suggested, I think by Mr. Sydney Hollan that the Government might with propriety subsidise th hospitals by an augmentation of their revenue from publ funds equal in amount to the total of the voluntary co tributions; and it has often been suggested that hospita fulfilling certain conditions of usefulness and efficien might with propriety be exempted from the payment of loc rates. It seems to me that the adoption of one or both these suggestions is eminently desirable in the interests the public and that only by adopting one or both of the could control in the public interest be secured without th sacrifice of independence. It is a national scandal that th hospitals receive no subvention, and that the persons able contribute to their support, but who wholly fail to do s nevertheless share equally with contributors in the benef which they confer upon the entire community. Antisep surgery is as much at the command of a miser who nev gave a shilling to a hospital in his life as it is at that of M Herring himself. I should rejoice to see the miser reached b the tax collector or by the rate-collector, but any notion direct or complete hospital control by the Government or t a municipality is unthinkable. No one could endure to s St. Bartholomew's reduced to the condition of the War Offi or to see the municipality of Marylebone turn away i attention from electric lighting to the management of th Middlesex Hospital.

The distribution of a Government subvention or the gra of immunity from local rates would require, of course, to b supervised by some competent authority, and would perm the Government of the country to appoint one. It should, think, be a commission of three persons, comparable to th Charity Commission, and should be a paid body with n other official duties or responsibilities. Its business sho be to make itself thoroughly conversant with the manag ment of all hospitals which through their secretaries committees expressed a desire to participate in the su vention or the immunity which it was the function of th commission to administer, and to lay down the conditio under which such participation might be obtained. It should have no power of interference where its assistance was not sought, but absolute power of assent or refusal when an application for assistance was made, and in this way I conceive that its influence upon administration would soon become paramount. The commission would be able to use the funds or the immunities at its disposal as levers for the production of necessary reforms; and it would do this without wounding susceptibilities or alienating friends. It might say to a hospital deriving the bulk of its patients from a distance that it should be financially assisted on condition of going to a locality where it was more wanted, and such a decision would be at once a stimulus towards removal and a justification for an appeal for the necessary means. It might say to three or four special hospitals for the same infirmity that their separateness entailed unjustifiable waste of money, and might thus practically force them to combine; and it would be able to offer sufficient inducements for the accomplishment of desirable changes of many other kinds. It might powerfully check recourse to hospitals by persons able to pay for treatment. Its chief distinguishing feature would be that it was composed not of amateurs but of officials whose daily work and duty it would be to probe all questions of hospital administration and government to the bottom and to bring them to the test of well-established principles. There would be no interference with internal management or with individual committees, in a word no objectless or vexatious meddling, but a steady influence making for administration in the best interests of the public and of science, and exerted by men whose *quasi* judicial positions would be a guarantee of their aloofness from personal squabbles or disputes. A hospital which refused to comply with the conditions laid down by such commissioners would at once be placed upon its defence before the public, and would be called upon to satisfy individual supporters, or the distributing committees of the funds, with regard to the justification which might be pleaded for the position it had assumed. Government subvention or assistance may be a long way off, but I think it is certain to come at last and that it ought to be both sought and welcomed. The hospitals constitute a great national interest, to the maintenance of which every citizen ought in some measure to contribute, on which the community is entirely dependent for the advancement of medical and surgical science, for the provision of skilful medical aid either for individuals or for the public services, and even for the counsel which Governments are sometimes driven to seek from the profession, but for which it is their highly moral custom strictly to abstain from payment. Subsidies, scanty indeed, are given to universities, but they are sufficient to establish the principle, and they have shown that such subsidies need in no way interfere with independent management or with natural development. I look forward to a time when hospitals will be similarly assisted; and until that time arrives I do not believe that any useful central control of them will be attained.

I am, Sirs, yours faithfully,
Jan. 19th, 1904. HOSPITAL SURGEON.

THE CHOLERA EPIDEMIC IN SYRIA AND MESOPOTAMIA.

(FROM THE BRITISH DELEGATE TO THE OTTOMAN BOARD OF HEALTH.)

SINCE the date of my last letter to THE LANCET[1] there has been a serious diffusion of cholera from Syria down the valley of the Euphrates to Mesopotamia and to one at least of the holy burying places of the Shiah sect of the Moslem religion. At the time I last wrote (August 20th) the outbreak was almost confined to the vilayets of Syria and Aleppo, and the news had been just received of the appearance of the disease at Biredjik on the Euphrates. Absence from Constantinople during the past few months has prevented me hitherto from continuing the story of the epidemic, and I propose to do so now, taking it up from the date of the letter referred to. In the vilayet of Syria cholera remained active throughout the months of August and September, was somewhat less so in October, and by the end of November had almost though not quite disappeared. The following table shows the course of the disease in Damascus, as compiled from the official returns. It is a continuation of the table on p. 1040 of the last volume of THE LANCET.

CHOLERA IN DAMASCUS.

Date.	Cases.	Deaths.
From August 9th to August 15th	63	54
" " 16th " " 22nd	104	78
" " 23rd " " 29th	76	53
" " 30th " Sept. 5th	156	89
" Sept. 6th " " 12th	76	64
" " 13th " " 19th	92	54
" " 20th " " 26th	138	112
" " 27th " Oct. 3rd	131	110
" Oct. 4th " " 10th	143	101
" " 11th " " 17th	67	53
" " 18th " " 24th	22	20
" " 25th " " 31st	7	3
" Nov. 1st " Nov. 7th	2	2

The last case of cholera was believed to have occurred in Damascus on Nov. 5th. The remarkably fluctuating character of the numbers of cases in the above table can scarcely escape notice. The numbers of deaths are more trustworthy and they indicate that the outbreak reached its highest point in the latter half of September and first week of October.

Although cholera was active in many parts of the Aleppo vilayet as early as the second half of July it was not until Sept. 5th that the disease was recognised in Aleppo itself. On that day a youth employed in a pork butcher's shop was found to be suffering from cholera in its severest form. The course of the disease in Aleppo is shown in the following table:—

CHOLERA IN ALEPPO.

Date.	Cases.	Deaths.
From Sept. 4th to Sept. 6th	2	0
" " 7th " " 13th	9	7
" " 13th " " 19th	37	46
" " 20th " " 27th	53	50
" " 28th " Oct. 4th	35	31
" Oct. 5th " " 11th	44	39
" " 12th " " 18th	82	62
" " 19th " " 25th	59	64
" " 26th " Nov. 1st	46	50
" Nov. 2nd " " 8th	16	15
" " 9th " " 15th	0	0
" 21st	1	0
From " 22nd " " 29th	32	22
" " 30th " Dec. 3rd	13	12
" 7th	0	2

The remarkable lull in the epidemic at Aleppo after the first week of November, and its equally remarkable revival in the third week of that month, have not as yet been satisfactorily explained. The lull is not to be ascribed to the absence of definite news. From Nov. 7th to 21st daily bulletins were received stating positively that there were no cases in that city. But on the 21st one case was reported; on the 24th there were four cases; on the 25th, five cases; on the 26th, seven cases; and on the 27th and 28th respectively, four cases and eight cases. Then the outbreak again subsided. From Dec. 7th to Jan. 5th Aleppo was believed to be free from cholera but on the latter date a single case was observed there.

In the meantime the disease was continuing more or less active in many other places of both the vilayets of Syria and Aleppo It is scarcely possible, and would perhaps serve no very useful purpose, to trace in detail the course of the epidemic in all the innumerable towns and villages where it has made its appearance. Its course has been irregular and uncertain. It has in many instances disappeared—or has seemed to disappear—from a place only to reappear after a longer or shorter interval. An example of this has just been seen in Aleppo and even more striking instances of the kind might be quoted from the experience of other places. It is worth noting, however, that cholera has now been more or less continuously present in Syria since the end of September, 1902. It has fluctuated from time to time and in February, 1903, it was hoped that it had really disappeared, as for a whole month no cases were officially reported from any town or village in this portion of the Turkish Empire. But the hope was not realised; the disease broke out again as badly as ever and as no fresh importation of infection was ever proved, or even seriously suspected, it is practically certain that the cholera virus has never been absent from these regions for the past 15 months.

---

[1] THE LANCET, Oct. 10th, 1903, p. 1040.

Apart from the great and populous centres, such as Damascus and Aleppo, already briefly dealt with, the greatest interest attaches—from the point of view of the defence of Europe against an invasion of the disease—to the behaviour of cholera in the ports of the Syrian littoral. Before turning to this aspect of the question, however, it will be useful to give a summary of the total cases and deaths which have been officially reported from all places in the affected regions since the revival of the epidemic in March last.

	Totals	7687	6527

The high figures in the second and third weeks of December were caused by the severe outbreak of cholera in Kerbela to which detailed reference will be made later. The totals in the above table must be regarded, on the evidence of unbiased witnesses, as considerably below the truth. From many places no returns at all have been received and when statistical returns have been received from other places there has frequently been positive proof from collateral sources that these fell considerably short of the actual numbers of cases and deaths. It is difficult to say how far short of the truth the official figures have fallen, but probably a moderate estimate would place the total cholera mortality in the last nine months in the Turkish Empire at not much less than 10,000.

The principal ports on the Syrian coast have suffered less than towns or villages in the interior. In Tripoli cholera was present from July 22nd to Sept. 13th. The following figures for Tripoli are in continuation of those published in my last letter.[2]

Date.	Cases.	Deaths.
From August 16th to August 22nd	89	67
,, ,, 23rd ,, ,, 29th	22	27
,, ,, 30th ,, Sept. 5th	44	4
,, Sept. 6th ,, ,, 13th	6	5

There followed a whole month during which Tripoli was declared day by day to be quite free from cholera but on Oct. 13th five cases with one death were reported to have occurred in the upper portion of the town. The patients were all inhabitants of the town; the first of them was taken ill on the 12th. The source of the infection was at first a mystery but it was subsequently shown that it had been reintroduced to Tripoli by persons coming from the *caza* or district of Akkar, where cholera was then present. From Oct. 13th to 21st 22 cases with 17 deaths were reported. Then the disease again disappeared; but on the 28th a single, imported, fatal case was observed and on Nov. 12th six fresh cases were suddenly reported. From Nov. 12th to 22nd, when cholera disappeared, it is hoped finally, from Tripoli, there were 31 cases and 25 deaths.

In Alexandretta a single imported case of cholera, followed by death, occurred on Sept. 5th. The patient was a camel driver who had come from the interior. Four more cases occurred on Oct. 12th. While Alexandretta escaped so lightly, cholera caused a considerable mortality in a number of villages in its neighbourhood, and at Payar, on the coast, five fatal cases occurred on Sept. 20th and 21st.

At Beirut only imported cases of cholera have been observed. The two cases brought by refugees from Tripoli on board sailing ships, which occurred in August last, were described in my last letter. Since then two exactly analogous cases have occurred. The first was that of a sailor on a small sailing ship of three tons, called the *Mabruca*, which arrived at Beirut on Oct. 25th. There were only three men on board and one of these was attacked with cholera two days after her arrival and died the same night. She had come from Suédié, where cholera was then present. The second instance occurred on Nov. 6th. The patient was a passenger on another sailing ship of the same name—the *Mabruca*—which had arrived the day before from Arvat, an island near Tripoli. It was from this island that the first imported case of cholera at Beirut in August last had sailed and though the presence of the disease on the island was never proved, it is at least remarkable that later an outbreak of cholera occurred in the Tarsous district, on the mainland but facing the island. The disease appeared there early in November but the extent of the outbreak was not known.

At Caiffa (or Haifa) three fatal cases occurred in one house on Oct. 25th. From that date to Nov. 17th 15 cases and 12 deaths were recorded there. At Latakia cholera did not make its appearance until so late as Dec. 21st. Between that date and the 29th of the month ten cases with seven deaths were reported to have occurred there.

It will be seen from the above brief summary that, as already stated, the Syrian coast ports have escaped with comparatively light visitations of cholera, while in the interior that disease has been causing very serious ravages. I propose now rapidly to trace the course of the epidemic northwards and eastwards.

Throughout the latter half of the year just ended, while there have been a considerable number of infected centres in the vilayet of Syria proper, it has been in the more northerly vilayet of Aleppo that the disease has been most active. At Antioch cholera was first detected on Sept. 16th. The recorded mortality was never very high there. The deaths in Antioch in the successive weekly bulletins, beginning with the week ending Sept 21st, have been as follows: 3, 9, 8, 12, 10, 15, 50, 7, 6, and 8. The highest figure fell in the week ending Nov. 2nd and the last recorded case was on Dec. 7th. Two days later than the appearance of cholera at Antioch it was reported from Aintab, an important town some 60 miles to the north of Aleppo. From Sept. 23rd to 27th there were 17 cases and eight deaths there. Then followed in successive weeks 24 deaths, 14, 6, 4, 4, none, 2, none, none, and 1 death respectively.

The outbreak of cholera at Biredjik, on the Euphrates, was mentioned in the postscript to my last letter. The fear there expressed that the disease would spread thence to Armenia and Mesopotamia has been unfortunately realised. The first cases occurred in Biredjik on August 16th; the week of highest mortality was that ending on Sept. 19th, when 19 deaths were reported. Cholera appeared at Orfa (or Urfa) on August 22nd. *Orfa* is in Mesopotamia and about as far to the east of Biredjik as Biredjik is of Aintab. The numbers of cases and deaths in Orfa in successive weekly bulletins have been as follows: 14 cases and six deaths in the week ending August 31st; then in the subsequent weeks 12 and 12, 8 and 4, 12 and 14, 33 and 25, 31 and 30, 24 and 21, 42 and 29, 21 and 15, 12 and 17, 4 and 2, and 5 and 5 respectively. The last known case of cholera occurred in Orfa on Nov. 7th. In all not far short of 200 deaths were recorded there; the last group of five cases and five deaths occurred among nomad tribes encamped in the neighbourhood.

---

[2] THE LANCET, Oct. 10th, 1903, p. 1042.

From Orfa or Biredjik cholera has spread on the one hand northwards and eastwards to the important town of Diarb[illegible] to Anah, Kerbela, [illegible] the disease in Diarb[illegible] other places named it may be most conveniently considered first. There is, indeed, evidence that though unrecognised by the local authorities, cholera was present in Diarbekir as early as September and therefore considerably before it was believed to have spread down the Euphrates. The first official news of its appearance in or near Diarbekir was received on Nov. 20th, when it was reported that about a fortnight before the disease had appeared in the village of Habesh, some 15 miles away, and that 35 cases with 20 deaths had occurred there. Consular reports confirm this outbreak and state that the village is named Habeshi, that it is inhabited by Kurds, and that cholera was taken there by some camel-drivers from Aintab. One of the camel-drivers died, the corpse was stripped, as part of the funeral rites, the clothes were distributed, and the epidemic followed. The course of the disease in Diarbekir itself is uncertain. Consular reports state that it broke out there in September when it caused 16 deaths, six of which occurred in the American orphanage and two in the barracks. The local authorities refused to admit that the disease was cholera and no mention of this outbreak has been made in the telegrams to the Sanitary Administration in Constantinople. That administration has no permanent medical officer in Diarbekir but an officer sent there on special mission reported on Nov. 18th that on that date three soldiers had been admitted to hospital suffering from cholera. Two of these died. Then for three weeks there were said to have been no more cases. But on Dec. 15th four fresh cases were reported and on the 17th there were as many as 29 cases and ten deaths. This was a short but sharp outbreak. It lasted just one week, during which 54 cases with 32 deaths were reported. On one or two days no reports were received, so that the true figures were probably higher.

The first town of importance on the Euphrates below Biredjik where cholera is known to have made its appearance is Anah. This is a town of some size situated between 250 and 300 miles below Biredjik. Four cases of cholera were detected there on Oct. 29th. It was subsequently ascertained that among a group of persons who had come by raft from Biredjik to Anah a death had occurred and that the body had been buried at Anah. The first recognised case of cholera occurred there in a house adjoining the place where the body had been buried and the disease spread thence through the town. The following are the numbers of cases and deaths reported from Anah:—

Date.	Cases.	Deaths.
From Oct. 29th to Nov. 2nd	51	93
,, Nov. 3rd ,, ,, 7th	76	80
,, ,, 8th ,, ,, 10th	28	25
,, ,, 11th ,, ,, 17th	51	56
,, ,, 18th ,, ,, 19th	16	12
,, ,, 20th ,, ,, 27th	12	11
,, ,, 28th ,, Dec. 3rd	2	1

Since the last date named no positive news has been received from Anah, but at Rava, to the north and on the opposite bank of the river, a fatal case occurred on Dec. 23rd and another on the 24th.

Of far more serious import was the [illegible] Kerbela, one of the holy [illegible] Kerbela is situated on a [illegible] distance to the west of the [illegible] 32 and 33 north. [illegible] of pilgrimage of t[illegible] there in enormous numbers during their life and whose one hope is to be buried there after their death. The town of Kerbela is one vast cemetery, or to be more accurate, a vast network of underground vaults in which the bodies are deposited in their coffins, not buried in the earth. The corpses are brought from all parts of the Mahomedan world but principally from Persia and India. The law requires that death shall have taken place at least three years before the body is buried here but the law is constantly evaded and corpses are brought for burial in every stage of decomposition. The first news of the appearance of cholera in Kerbela was received on Dec. 11th. Five cases had then been observed. On the 12th there were 46 deaths and on the 13th as many as 84 The outbreak was believed to have come to an end on the 23rd of the month. The numbers of cases are not accurately known but the number of deaths officially reported exceeded 600. Among the measures taken to control the outbreak was the prohibition for both pilgrims and corpses to enter Kerbela and all communication with Nedjef was cut off. Fortunately, the disease did not appear in the latter and last week, in view of the accumulation of pilgrims in Nedjef and the fe[illegible] and force the cord[illegible] pilgrims (but not of [illegible] They are permitted to go there, however, only in groups of 200 at a time.

In the immediate neighbourhood of Kerbela cholera has attacked a few persons at Hindieh. At Musseyib, on the right bank of the Euphrates and considerably to the north of Kerbela, seven deaths from the disease occurred on Dec. 16th among persons detained in the lazaret there. Cases began to be observed in the town about the same time. 3000 pilgrims were reported to be collected on the opposite bank of the river and a few cases occurred amongst them. The later news from Musseyib has been very incomplete and there is positive evidence that many cases have occurred there which have not been reported.

On Dec. 26th it was reported that a suspicious disease had appeared in Mossul, on the Tigris, about half way between Bagdad and Diarbekir. On the 28th nine cases—all fatal—of this disease were stated to have occurred. On Jan. 1st another fatal case was reported and it was admitted that the disease was cholera. The only news since received from Mossul is that no fresh case has occurred there "since Jan. 6th."

Bagdad appears to have been infected with cholera at least since Dec 31st and probably longer. On that date the sanitary authority reported having seen a case indistinguishable from true cholera and added that other practitioners in the town had seen similar cases during the preceding eight days. On Jan. 7th it was reported that this case had died and that there were persistent rumours in the town that several deaths from a similar disease had occurred and the bodies been secretly buried.

The cholera epidemic as a whole is probably now at its lowest point. Yet there is constantly recurring evidence that the infection is still widely present. The vilayets both of Syria and Aleppo and the valleys both of the Tigris and Euphrates are more or less infected throughout. A serious revival and extension of the disease in the spring are almost inevitable. Fortunately the Hedjaz is, so far as is known, quite free from it and it may be hoped that this year's pilgrimage will escape without an outbreak of cholera.

Constantinople, Jan. 12th.

LATIN-AMERICAN CONGRESS OF MEDICINE AND HYGIENE.

(FROM OUR BUENOS AYRES CORRESPONDENT.)

THE Second Latin-American Medical Congress will be held at Buenos Ayres in April next. It will be opened on April 3rd and will close on the 10th as regards the Medical Congress, but the Exhibition of Hygiene, which is to be inaugurated at the same time, will remain open until May 30th.

The first Congress, which was held in 1901 and was reported in our columns, was a great success and the second Congress, judging from the preparations which are being made and the number of adherents who have registered, promises to be even a greater success. Over 300 Argentine medical men and sanitary engineers have sent in their names and the delegates from the other South American republics will probably number over 100, such distant places as Ecuador, Honduras, Colombia, and Mexico being well represented. The city of Buenos Ayres, from its great size, wealth, commercial and scientific activity, and its high reputation for lavish hospitality, is well adapted for a big congress, and no European scientific man who thinks of going there need fear any such want of organisation as was evident at Madrid last year. The Exhibition of Hygiene is a new feature and promises to be an interesting and valuable addition.

Of all Latin cities, not even excepting Paris, Rome, and Madrid, Buenos Ayres is easily foremost in matters hygienic. The huge drainage and water systems have been carefully planned and carried out by eminent English engineers and contractors at enormous expense, while the cleaning of the streets and the regulations for markets, lodging-houses, traffic, ambulance first aid, vaccination, compulsory notification of diseases (including tuberculosis), &c., have all been based by the municipality on the best systems at work at present in London, Paris, and Berlin. Not having any national tradition to keep up and not being hampered at every step by a fatherly Parliament, the municipality, aided by the advice of the National Council of Hygiene (Local Government Board), plans and orders the construction of houses and regulates the life of the individual. The opening of an Exhibition of Hygiene in such a city will, of course, be of great interest and value to the other and smaller South American States.

The following is a list of the principal medical communications already promised and some of which have been sent in, those marked with an asterisk promising to be of special interest:—A Study of the Different Systems for the Sanitation of Cities, Dr. Aragon (Mexico); the Utility of Studying Medical Technicality with the View to Forming a Permanent Committee for its Study and Application, Dr. Terry (Mexico); Extra-Uterine Pregnancies, Dr. Correa (Chile); Operations for Cancer of the Uterus, Chile, Dr. Kosner; *Analytical Study of Parturition and the Fœtus in Chile, Dr. Oliva; Urgent Surgical Interference in Grave Injuries and "The Surgical Complications of Dental Caries, Dr. Bazterrica (Chile); *Climatology and Demography of the Magellan Straits, Dr. Avaria (Sandy Point); *Twenty Years of Clinical Statistics in Eye Diseases, Chile, Dr. Cienfuegos; *Bubonic Pest in Chile, Dr. Cadiz; *Epidural Injections in Certain Urinary Diseases, Chile, Dr. Monteso (Chile); Differential Diagnosis of the Various Intra-abdominal Murmurs, Dr. Cadiz (Chile); Dementia (Precocious), Dr. Etchepare (Montevideo); Hydatid Cysts, Dr. Oliver (Montevideo); *Etiology, Clinical Forms and Geographical Distribution of Leprosy in America, Dr. Foreati (Montevideo); Tuberculin as a Method of Diagnosis in the Tuberculosis of Children, Dr Martirene (Montevideo); Biliary Lithiasis and its Complications, Dr. Poney (Montevideo); *Propagation to Man of Certain Parasitic Diseases, not Microbic, existing in South American Cattle, Dr. Berger; *International Prophylaxis of Yellow Fever, Dr. Lacerda (Rio de Janeiro); *Progress in Public Sanitation in Latin America, Dr. Sosa (Lima); *International Prophylaxis of Plague, Dr. del Rio (Chile); *The Results of the Compulsory Notification of Transmissible Diseases in Latin America, Dr. Canabal (Montevideo); *The Epidemiology of Malaria in the Argentine Republic, Types of Malaria Parasites, Parasites antagonistic to Quinine, The Problem of Disinfection of the Blood in Malaria, Dr. Delfino (Rome); *Hydatid Cysts in the Argentine Republic, Dr. A. Vega; *Frequency of Cancer in America, Dr. Bunge; *Infantile Tuberculosis in America, Dr. Araoz Alfáro; *Leprosy in America, Dr. Farini; *Yellow Fever, Dr. Penna; Carbuncle (Anthrax), Dr. Mendez; Framboesia, Yaws, &c., Etiology, Forms, and Geographical Distribution, Dr. Sommer; *Alcoholic Mania in America, Dr. Cabred; besides communications on Actinomycosis in the Argentine Republic, Malignant Early Syphilis, Malignant Neoplasms of the Skin, *Infantile Feeding in Relation to Rickets and Warloff's Disease in America, Physiology of Physical Exercise, Physiological Pathology of Tremors, *Penetrating Wounds of the Chest, Treatment of Prostatic Hypertrophies, Pelvic Suppurations, &c.

The subjects chosen for open discussion are very interesting and are as follows: (1) Causes of Deaf-mutism in the Argentine Republic; (2) Prevention of Blindness; (3) the Etiology of Goitre; (4) X Rays in Surgery; (5) Distocia in the Argentine Republic; (6) Hæmatology in Surgery; (7) Strictures of the Urethra; (8) Surgical Interference in Exophthalmic Goitre; (9) Treatment of Cancer; (10) Treatment of Laryngeal Tuberculosis; (11) Treatment of Tuberculosis of the Eye; and (12) Biliary Lithiasis and its Complications.

It will thus be seen that important papers will be read on yellow fever, plague, malaria, leprosy, tuberculosis, sanitation of cities, cancer, hydatid cysts, actinomycosis, and climatology, so that our knowledge of the above diseases as existing in tropical and semi-tropical countries should be correspondingly increased.

The Exhibition of Hygiene will be very complete in maps, drawings, models, and statistics. The official language is Spanish but French is well understood by all the educated people. All the steamer lines from Europe offer reductions of 30 per cent. on return tickets. April will be autumn in the Argentine Republic and the season favourable, but the harvest being over visitors will not be able to see the hundreds of square miles of wheat, maize, and flax which are one of the wonders of that land but they will be able to see thousands of sheep and cattle frozen daily in Buenos Ayres for export to Europe.

MALAGA AS A WINTER RESORT.

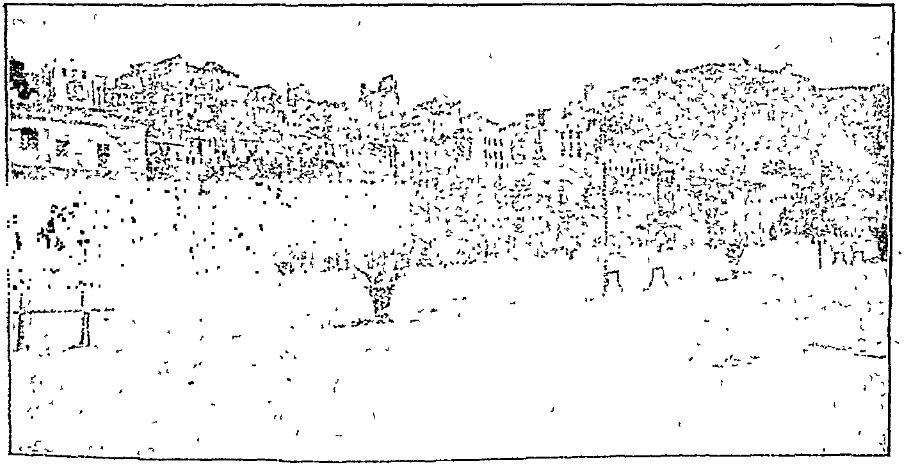
(FROM OUR SPECIAL SANITARY COMMISSIONER.)

GIBRALTAR direct by steamer from England can now be reached within four days. From Gibraltar the ferry boat conveys passengers to the Algeciras station in half an hour. Here a line, recently built by English engineers, connects with the main lines at Bobadilla Junction, where there is a good buffet and lunch can be obtained before taking the train for Malaga. It is, however, better to sleep at Algeciras. There are two very good hotels and by taking the early train Malaga can be reached in the afternoon after a daylight journey through some of the most romantic and beautiful mountain scenery of Andalusia. Indeed, the line from Bobadilla to Malaga traverses the Switzerland of Spain; it also enables the traveller to appreciate the mighty mass of mountains that shelter Malaga from the northerly winds. Thus it is that at Malaga, as on the French and Italian Rivieras, the vegetation is that of countries of more southern latitudes. After passing through 11 tunnels the wonderful and wild gorges of the Hoyo, which in Spanish means a hole or pit, the train descends into the fruitful *vega de Malaga*. Here the figs ripen early in June. The sugar-cane and the cotton plant thrive and also the sweet potato (*batatas*) and the custard-apple (*anona cherimolia*). Of course the melon, the pomegranate, the Japanese medlar, the prickly pear, the olive, the orange, and the lemon all ripen luxuriantly round and about Malaga but these sub tropical fruits also abound further north on the French and Italian Rivieras. Malaga being much more to the south ought to, and does, possess a vegetation that cannot be found even in the most favoured spots of the Riviera. There is consequently a distinct climatic difference and this, in certain cases, may afford an advantage over the ordinary and nearer winter resorts. The principal obstacle is the overland journey through the whole length of both France and Spain which is a very irksome undertaking. Of course, it is pleasant enough for those who can afford to travel by short stages, as there are many towns of great interest to be visited on the road. This, however, would hardly suit a patient whose chief object is to obtain, with as little fatigue and effort as possible, a complete change of climate. On the other hand, those who can stand the sea are likely to benefit by the rest and luxurious comfort of the manificent steamers that stop at Gibraltar on their way from England to the far East. As already pointed out, the journey from Gibraltar to Malaga is not long and can be accomplished by daylight.

It is perhaps scarcely necessary to expatiate on the merits of the climate of Malaga. The Malaga muscatel raisins that adorn our Christmas dessert are in themselves a sufficient witness. The proximity of the sea mitigates the extreme heat, while its southerly position and the shelter of the mountains prevent the advent of cold weather. Thus snow and frost are almost unknown and the thermometer, even on wintry nights, rarely falls below 50° F. Then there is hardly any rain. On an average rain does not fall on more than 30 days in the year and it only lasts for a few hours. But there are exceptions and then damage is done by an excessive downpour. The one thing to be feared is a land wind called the *tarral*. From the heated plains of the interior it produces in summer excessive and unpleasant dryness, while in winter it brings cold from the snow clad sierras. This wind, however, never lasts long and constitutes a the only fault that can be found with the climate of Mal Invalids are obliged to keep indoors when the *tarral* blowing. It comes from the north west and descends the Sierra de Abdalajis through the Hoyo, following the course *of the railway line—in other words, it is the mistral* of the Spanish Riviera. But just as on the French Riviera there are chosen spots that are almost completely sheltered from the *mistral*, so there must be eligible sites near Malaga that are equally protected from the *terral*.

Unfortunately the excellence of climate is not the only thing needed. The effects of the best of climates can be destroyed by bad hygiene and the death-rate at Malaga is appallingly high if we look only at the figures given. To speak of Malaga as a health resort when there is a death-rate of about 38 per 1000 per annum of the population seems like a misuse of terms. Yet it would be a mistake to consider that these statistics proportionately affect the class of patients likely to go to Malaga from England. There are certain things in the sanitation of a town that concern all alike, whether rich or poor, such, for instance, as the water-supply. Now Malaga has a very good water-supply. English and French capitalists and engineers contrived to surmount many and manifold difficulties and finally succeeded in installing extensive waterworks. The waters of the Torre Molinos were covered over at their source and taken to Malaga in large iron pipes. Thus pure water is delivered at the doors of the houses. It is true that for a considerable time private wells were allowed to subsist and these were dangerous, but since the great cholera epidemic of 1885 they have been closed. Now the only danger in regard to the water-supply is that it may get contaminated when inside the house. There are small cisterns still used within the houses and these may be dirty; mice and other animals may fall into them. But the same objection can be made to the London water supply, for in many parts of the metropolis the old and more or less dangerous intermittent supply with cisterns still exists.

The drainage of Malaga is certainly in a very defective condition. The sewers have in many cases insufficient fall and there are no good means of flushing them, so that deposits causing effluvia abound. It is only in some houses that the closets communicating with these sewers are efficiently trapped. Nevertheless, the desire to have proper sanitary closets is growing and they are now much more general than they were a few years ago. The municipality is unfortunately very much in debt, so that it would be difficult to carry out a comprehensive scheme of drainage Still some progress has been accomplished. For instance, many of the small streets have been covered over with asphalt. These thoroughfares abutting on the most fashionable and best streets were a great nuisance. The ground was sodden with every sort of filth and garbage. Even energetic scavenging could not really clean these places for the moist soil retained the worst part of the dirt. Now all is covered over with impervious asphalt, so that any rubbish can be effectively swept and washed away and there is no infiltration into the subsoil. But by far the greatest improvement, and this was a gigantic undertaking, has been the construction of the new harbour. A large amount of foreshore has been reclaimed and a sea wall has been built so far forward that the ships, instead of riding at anchor, can now come alongside When the water came far up into the land the deep parts were at a considerable distance from the shore and it was in this shallow water that the town drains emptied the sewage. The main outfall now passes close to, but outside, the sea wall or breakwater to the south-east Here a part of the channel is not covered over and therefore there are many bad odours. The outfall itself also does not go right out to sea. Indeed it is in an unfinished state and this work should be completed at once. It is quite evident, however, that the importance of such questions is not appreciated or this unfinished outfall would not have been allowed to remain in its present nuisance-creating condition and this too for a considerable time. What is better understood is the building of modern broad streets with fine, though commonplace, modern houses on each side and the laying out of public gardens. The prolongation of the Alameda to the new port, when the trees, the palms, and the other plants have had time to grow, will constitute one of the broadest, most handsome, and most picturesque sea fronts in existence. But here again the principal attraction is not appreciated. On one side there are the port, the shipping, and the sea. These are all interesting and beautiful but other and very fine ports and moles and piers can be seen elsewhere The view, for instance, from the Cannebière at Marseilles down into the old port, with its shipping, its many small levantine sails below, the white seagulls flying against the blue sky above, the old forts at the entrance of the antique, historic harbour, and the magnificence of the open Mediterranean beyond constitute a picture which the new port of Malaga cannot equal



Malaga View inland from the prolongation of the Alameda to the new port.

On the other hand, if the visitor turns his back to the sea and from one of the Malaga breakwaters or from the new prolongation of the Alameda looks inland, a view will be obtained that is unique. Covering the dome shaped hill to his right are still standing the grim battlements of the Castillo de Gibralfaro. At a lower level and rising above the surrounding houses are some formidable Moorish towers. These are the remains of the palace fortress called the Alcazaba and it is connected *with the* Gibralfaro by double walls. Here was the settlement of the early deserted and [illegible] people have gone to live in the abandoned quarter and there are scenes of squalor and much dirt on all sides. Yet these hills should be one of the chief attractions of Malaga. Rubbish should be cleared away, the best parts of the ruins well exposed, flower-beds planted near, and the whole quarter converted into a promenade after the fashion of the Alhambra at Granada. Here are ruins of real interest to the historian, the archæologist, the architect, the artist, and the ordinary tourist who can appreciate the beautiful and the romantic. They are priceless; all the money in the world could not reconstitute the history represented by these time- and war-worn battlements, but a comparatively small sum would suffice to preserve them. If they were rendered accessible to visitors, if their history was revived, and interest awakened the increase in the number of tourists passing through Malaga would soon pay for the small cost incurred. But this is not in the least understood and most of the town people very much prefer building ugly modern houses to preserving these most picturesque ruins. Yet they should bear in mind that there are no attractions in the town of Malaga. There is nothing to see. Had the Moorish mosque been preserved that would doubtless have brought many visitors, but the cathedral built on its site is a nondescript building principally remarkable for its size. The old Alameda is certainly a spendid thoroughfare and promenade, but its beauty is due to its many trees rather than to the buildings on either side.

It is the country around rather than the town itself which constitutes the chief charm of Malaga The semi-circle of mountains that spread out fan-like to shelter Malaga is about 50 miles in length. On the offshoots of these mountains and close to the seashore there are suburban districts which will doubtless constitute the health resorts of the future. Already a tram-line follows the coast far beyond the town. Here a hotel has been built for those who wish to live well away from the town. It overlooks the sea and on the other side there is a plain sheltered by mountains. All along this road there is a succession of fine views, and at some distance can be seen the hill from which Malaga derives its excellent water-supply. This is important, for it means that good water can be delivered to all the houses that are gradually springing up on this coast-line. At present there is plenty of space here. Of course, there are no sewers but there is open country and there is room for cesspools to be built well away from the houses; in any case, it is virgin soil that has not been polluted by previous occupants; indeed, in many places the sea used to come up the hillside and there was no place whatsoever for building. Other parts which used to be safe have now to be protected by sea walls. The fact is that something like half a mountain has been blown up and the material carted away to build the new port. The jutting out into the sea of the artificial breakwater has caused a swirl and backwash which have attacked some parts of the coast that used to be safe. In course of time a railway will supplement the present tramway communications, so that there will be a seaside country district created within easy reach of the town. As all the villas built there, or likely to be built, are beyond the town *octroi* or dues the cost of living will be cheaper.

Nevertheless, the town itself is the real centre and its sanitation must be improved. Dr. Don Ramón Martin Gil has proposed that sea water should be pumped to the top of the castle hill and from there used to flush the sewers. But then there are 95 streets that have no sewers whatsoever. In some places there still remain cesspools that are very porous and which allow the surrounding subsoil to be contaminated, but the inhabitants for the most part ignore these facts or altogether fail to appreciate their importance. A branch

enforced. But all these imperfections and the greatest possible ignorance and indolence cannot alter the wonderful climate prevailing on this coast-line. The sanitary defects of the town can be avoided by living outside, as Mr. Clarence Visick, the local British practising physician, generally recommends. Then for shopping and social purposes the new streets of Malaga and the newly paved old streets are all clean and as free from unpleasantness as in most fairly well-ordered towns. There are also some excellent and very clean hotels with the usual moderate charges that obtain in the provincial towns of Spain. So that altogether the invalid wintering at Malaga may rely on being able to enjoy the benefits of the climate while insuring but a minimum of risk in regard to defective sanitation if he selects with some judiciousness his place of residence.

LIVERPOOL.

(From our own Correspondent.)

Demolition of Insanitary Areas in Liverpool: No Small

There were 378 deaths during the week ended Jan being equivalent to an annual mortality of 27·1 per 1 The number of deaths above the corresponding week of year (when the rate of annual mortality was 23·9 per 10 was 48. The increased rate of mortality was due to insanitary condition of a number of courts in the slu the death-rate in which varied from 63 to 83 per 10 Through the instrumentality of Dr. E. W. Hope, the medic officer of health, the health committee has already accom plished the demolition of large areas of insanitary proper where sickness and mortality were excessive, and he is no energetically urging the demolition of the above name insanitary dwellings. This insanitary property, as pointe out by Dr. Hope at the meeting of the health com mittee, is an unfortunate legacy of by-gone years and the city council had sanctioned a policy by which so many of the houses in question should be dealt with annually. If the requisite number were reached, as might reasonably be expected, they would within a fairly short time rid the city of those excessively insanitary blocks. The *Liverpool Daily Post* of Jan. 16th finds fault with the health committee and the housing committee for not being more alive to the necessity of more prompt action in the matter of demolition. Dr. Hope is, however, assured that the housing committee will effectually grapple with the difficulty. The city is once more free from small-pox.

University of Liverpool: Corporate Grant.

The finance committee of the city council has received an influential deputation representing the University in respect to the proposal that the city council should give financial assistance to the University. The deputation consisted of the Chancellor (the Earl of Derby, K.G.), Vice-Chancellor A. W. W. Dale, Sir John Brunner, M.P., and others. The Chancellor presented a memorial from the University praying for a grant in aid and each member of the deputation addressed the committee in support of it. The finance committee considered the subject after the deputation had withdrawn and eventually came to the unanimous decision to recommend the city council to grant the sum of £10,00 to the University during the year 1904, such sum to be pa out of the city rate.

Midwives Act, 1902: Recognition of the Liverpool Ladie Charity.

Under powers given to it the Central Midwives Board ha accepted the certificates issued by the Liverpool Ladies' Charity and Lying-in Hospital as qualifying the holder to be registered under the Act, and applications are being received for registration by the medical officer of health at the municipal offices, Liverpool. The Central Board has now taken a further step and has intimated to the board of management of the Ladies' Charity and Lying-in Hospital that the charity has been placed upon the list of institutions approved by it for the purpose of training pupils for qualification as midwives under the Act. The various committees of the charity are doing all in their power to take advantage of the privileges thus conferred upon them for the benefit of such persons as desire to devote themselves to the calling of a midwife.

Hospital Sunday Collection: A General Decrease.

The annual collections in aid of the medical charities were taken in the various places of worship on Jan. 10th. Unfortunately the weather in the early forenoon was raw and wet and the church attendances suffered considerably. To this cause must be attributed the general falling off in the amounts received. Very few places of worship, indeed, show an increase. The Ullet-road Unitarian Chapel, which generally heads the list, was £60 short of last year's collection. Altogether the prospects of reaching last year's general collection are far from promising Repeated protests have appeared in the local papers against taking the collection in the winter but the committee of the fund has given some valid reasons in favour of taking the collections early in the year.

Southport's Low Death-rate.

The medical officer of health of Southport reports that during the past year the death-rate of Southport was 14·65 per 1000 of the inhabitants, as compared with 15 32 in the previous 12 months. This rate is the lowest in the history of the borough. The purely local death-rate (excluding bad lives imported) was 12·92 per 1000, as against 13·20 per 1000 last year. The zymotic death-rate was 0·98 per 1000. This is a slight increase compared with the previous year, when the rate was 0·64 per 1000, but that figure was the lowest previously attained. Of the deaths 286 were those of people aged 60 years and upwards. The estimated population of Southport is now 48,000, though the Registrar-General places the population at a higher number. The birth-rate was 18 45 per 1000.

Jan. 19th.

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS.)

Proposed Reduction of the Salary of a Medical Officer of Health.

THE corporation of Aberavon, a Glamorganshire borough with a population of about 8000 persons, has suddenly shown a desire to curtail the expenditure of the town and as a first step has decided to reduce the salaries of the corporation officials, including the town clerk, the borough surveyor, the gas manager, the sanitary inspector, and the medical officer of health. This last-named official is Dr. J. Arnalt Jones who has been the medical officer of health for many years and receives a salary of £50 per annum, one half of this amount being refunded to the borough by the county council. At the meeting of the corporation at which these wholesale reductions were decided upon it was stated that last year there was paid as notification fees to the local medical practitioners no less a sum than £47 17*s*., which means that more than 380 cases of notifiable diseases must have occurred during the year in this small town which does not contain 1500 houses. About £20 of this sum was paid to the medical officer of health and several members of the corporation appear to consider that this was equivalent to an increase in his salary and a motion was accordingly proposed and carried that he be paid as medical officer of health £30 per annum, which sum should include his fees for notification certificates. In the very improbable event of this proposal receiving the sanction of the Local Government Board the Aberavon corporation would be paying no salary at all to their medical officer of health, for one half of the £30 would be paid by the county council and the other half would not equal the sum to which he would be entitled under the provisions of the Infectious Disease Notification Acts, always supposing that there was no considerable decrease in the number of cases of notifiable disease within the borough. Taking the county of Glamorganshire as a whole the salaries paid to the medical officers of health in the small towns and in the rural districts are distinctly below the average salaries paid in other counties of England and Wales.

A New Name for Workhouses.

There is a very creditable desire upon the part of many members of boards of guardians to reduce as far as possible any stigma which may be supposed to attach to residence in a workhouse. More than one board has made an unsuccessful attempt to designate its workhouse as an ordinary dwelling house by a number and the name of the street or road in which it is situated, more especially for the purpose of entries in birth certificates, and quite recently the Pontypridd board resolved to call its new workhouse in the Rhondda valley the "Rhondda Homes" and the Cardiff board proposed to call its auxiliary workhouse at Ely the "Ely Rest." The Local Government Board, however, insists that the name of the institutions shall in some way convey the idea of relief. In order, therefore, to meet the views of the latter body the institutions referred to will be known officially as workhouses, but the boards of guardians when speaking of them will call them by the names which they consider to be more appropriate.

Death of Mr. Edward Charles Garland, M.R.C.S. Eng., L.R.C.P. Edin.

Mr. E C. Garland, who died at Yeovil on Jan. 11th at the age of 69 years, was one of the oldest and most respected practitioners in Somersetshire. He was elected medical officer of health of Yeovil in 1872 and has been re-elected year by year since that date. A serious outbreak of scarlet fever in the borough during the autumn of last year threw upon him a great deal of extra labour, for he was especially interested in his public health work, and although he took a short holiday the strain of the epidemic appears to have affected him seriously. During the past few years Mr. Garland gradually relinquished private practice, devoting himself to the duties of medical officer of health and certifying factory surgeon. At the time of his death he was senior medical officer to the Yeovil district hospital and dispensary and medical referee under the Workmen's Compensation Act. Some articles from his pen have appeared in THE LANCET, the first of them being an account of a case of placenta prævia published in 1858. He leaves a widow, a daughter, and a son who is the Recorder of Winchester.

The Midwives Act.

The Gloucestershire county council has appointed Dr. J. Middleton Martin, the county medical officer of health and the medical officer of health of the Stroud urban and rural districts, executive officer under the Midwives Act at a salary of £105 per annum and out-of-pocket expenses. The Herefordshire county council has at present taken no action with regard to the administration of this Act.

Retirement of Dr. James Milward.

Dr. James Milward, who has been a Poor-law medical officer in Cardiff since the year 1867, has resigned his position as medical officer to the east district of the Cardiff union.

Bacteriological Diagnosis in Gloucestershire.

The bacteriological examinations required by the Bristol health department have hitherto been carried out in the municipal laboratory, but they are now intrusted to Professor Stanley Kent of the Bristol University College and at the last meeting of the Gloucestershire county council it was decided to pay to the college the sum of £105 annually in return for which medical officers of health in the county will be able to obtain from Professor Kent bacteriological examination of such specimens as they may send to him.

Vagrancy.

For many years past the members of the Gloucestershire county council have concerned themselves with the question of vagrancy within the county and by means of voluntary subscriptions certain tramps have been supplied with order tickets entitling them to a midday ration of bread in a distant town. In 1903 there were no less than 17 346 of these midday meals given out, an increase over the previous year of 4275. This increase is accounted for somewhat by the fact that there are extensive engineering undertakings being carried out at Avonmouth, at Gloucester, and at Winchcomb, and the professional tramp habitually follows in the track of the navvy. The standing joint committee of the county of Gloucester recently adopted the following motion and asked other county councils to consider the propriety of sending to the Local Government Board a resolution in similar terms :—

> That this quarterly meeting of the Gloucestershire standing joint committee views with great apprehension the progressive and serious increase in vagrancy in the country and respectfully submits that the subject should receive the careful consideration of the Local Government Board with a view to the establishment of a more effective and uniform system for dealing with tramps throughout the country.

Vaccination Expenditure.

At the meeting of the Bath board of guardians held on Jan. 13th it was reported that for the four years previous to the passing of the Vaccination Act of 1898 the vaccinations numbered 2100, the cost being £516, while for the four years subsequent to 1898 the vaccinations were 4403 and the expenditure amounted to £2052.

Jan. 18th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Small pox in Scotland.

THE following table shows the districts from which cases of small-pox have been intimated to the Local Government Board during the period from Jan. 1st to 15th inclusive :—

County.	Local authority.	Number of cases.
Ayr	Irvine burgh.	2
Dumbarton	Western district—

		199

During the last few weeks small pox has made its appearance in Edinburgh chiefly among the inmates of common lodging-houses. One or two cases have occurred in the Craigleith Poorhouse. There are now 20 cases in hospital. One of them, which proved fatal, was of the confluent variety and occurred in a Christian Scientist.

Edinburgh Royal Infirmary.

The adjourned general meeting of the court of contributors to the Edinburgh Royal Infirmary was held on the afternoon of Jan. 18th in the new council chamber. There was an attendance of about 150. The report by the committee of contributors was submitted to the meeting by Mr. James Haldane, C.A., the convener. In this report the question of age limit for the medical and surgical staff was dealt with follows: "The managers report that they have after mo careful consideration made a new rule to the effect that th ordinary physicians and surgeons shall in future retire reaching the age of 65. The contributors may be reminde that any new rule requires to be passed by the court of co tributors. At the meeting of contributors held on Jan. 4 a motion was carried which enacted a new rule putting th professors of the University who hold wards in the infirma on the same footing as regards an age limit as the medic and surgical officers who would be affected by the ne rule framed by the managers. That new rule, althoug referred to in the motion as to an age limit f professors and therefore possibly by implication approve of by the court of contributors, has not been formall sanctioned by the court and technically it may be open t question whether the new rule as to the professors was i order in being passed. The matter appears to the committe to be very difficult and delicate both as regards th physicians and surgeons and the professors, and th committee do not at this stage, at all events, presume t offer any opinion upon it; but in reporting to the co tributors on the proposed new rule, as they are by preceden bound to do, they venture to suggest to the contributors tha they should in the meantime delay to deal with the ne rule proposed by the managers and allow further time t consider the whole matter. It is of serious importance an ample time ought, in their view, to be allowed for considera tion and discussion. As regards the rule affecting the pro fessors it has to be observed that although it was carried b two to one only 69 contributors took part in the division and it seems most desirable that the whole question shoul be fully ventilated and that a more adequate representa tion of the views of the contributors should be obtaine on an important matter affecting the welfare of the in stitution. The committee beg to suggest that it might b desirable to appoint a small joint committee of the manage and members of the committee of contributors to conside the whole matter and make a report to a future meeting o contributors" After some discussion this suggestion from th committee of contributors was carried by 91 votes as agains 52 for an amendment proposed by Mr. J. T. M'Lennan, advocate, to the effect "that this meeting approve of th new rule with this exception—that the words 'nor to th professors' be deleted." The meeting was adjourned unt the last week in April.

Rectorial Address at the University of Edinburgh.

On Jan. 21st the Lord Rector of the University of Edinburgh, Sir Robert Finlay, M.P., delivered an address to the students of the University in the M'Ewan Hall in his capacity of Lord Rector of the University.

The Retirement of Dr. D. Argyll Robertson.

Regret will be felt by a large circle of friends in Edinburgh at the news of the early departure of Dr. Douglas Argyll Robertson who is about to remove to Jersey and to take up his residence there. A good many years ago Dr. Robertson gave up his lectureship in ophthalmic surgery in the Edinburgh Royal Infirmary, to which he was appointed in 1870, and he has gradually, I understand, been dropping out of numerous other positions and restricting himself to his private practice, which was one of the finest in the country. Douglas Argyll Robertson was born in Edinburgh in 1837, his father being a well-known surgeon of high standing. He received his education at various schools in Edinburgh, on the Continent, and at St. Andrews. His medical education was also obtained at various universities—Edinburgh, St. Andrews, Berlin, and Prague. He is a graduate in medicine of St. Andrews (1857), and a *Licentiate*, and afterwards a *Fellow*, of the Royal College of Surgeons of Edinburgh (1862). He selected the branch of ophthalmic surgery when he commenced practice in Edinburgh. In 1863 he was associated with the discovery of the properties of the Calabar bean as an ophthalmic agent, and in 1881 he was vice president of the ophthalmic section of the International Congress held in London. In 1869 and 1870 he made valuable discoveries in connexion with the eye symptoms in certain spinal lesions. Three years assistant surgeon in the ophthalmic department of the Edinburgh Royal Infirmary he was appointed in 1870 ophthalmic surgeon to that institution. Dr. Robertson had splendid physical powers and was an admirable athlete in his younger days, golf in particular claiming his attention. He was also an archer of the Royal Bodyguard.

The Case of Dr. J. F. D. Macara and the Parish Council of Durness.

Lord Pearson in the Bill Chamber of the Court of Session, Edinburgh, last week disposed of a note of suspension and interdict for Dr. James Findlay Duncan Macara, Durness, Lairg, Sutherlandshire, against the parish council of Durness with the object of preventing the respondents carrying out a resolution passed by them on Nov. 20th dismissing him from the post of medical officer of the parish. On March 31st and April 1st the complainer attended a pauper child named John Macpherson who was suffering from chicken pox and advised his mother to isolate him an [illegible] Macpherson, from school for [illegible] wards learned that in disregard of his advice the sister was sent to school and she was taken ill and was absent from school from April 9th to 20th. The complainer was not called in to attend her, however. The respondents directed him to certify to the head-master of the school as to the absence of Barbara Macpherson but he declined to do so on the ground that, while he was bound and willing to give such certificates to the parish council and the Local Government Board, he was not bound to give them to teachers or to the School Board. At a meeting of the parish council held on Nov. 6th two members were disqualified and thereafter, it was averred, the resolution complained of was passed by a majority of three to two, being confirmed at the meeting on Nov. 20th. The respondents stated that the complainer refused to supply their clerk with the certificate and maintained that in so doing he acted in breach of his duty. The disqualification of the two members of council was, they explained, entirely independent of the matter at issue between the complainer and them. His lordship passed the note and granted *interim interdict.*

Jan. 19th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Poor-law Medical Officers of Ireland.

AN important meeting of the Poor-law medical officers of the South Riding of the county Tipperary was held recently in the town-hall, Clonmel, for the purpose of forming a new branch of the Irish Medical Association and in support of the claims of the medical men. There was a large and representative attendance. The articles and by-laws of the county Wexford branch of the association were adopted and the question of the salaries of workhouse officers was postponed. A vote of thanks was tendered to Mr. R. F. Tobin of St. Vincent's Hospital, Dublin, and to Sir Lambert Ormsby for their advocacy of the claims of the Poor-law medical officers.

The Dangers of Overcrowded Theatres.

The public health department of the corporation of Dublin has issued summonses against the managers of the two principal theatres of the city in connexion with alleged breaches of the rules as regards means of egress laid down by the urban sanitary authority.

University Education in Ireland.

In response to a requisition signed by the Roman Catholic Archbishop of Dublin, Mr. John Redmond, M.P., and all the Parliamentary representatives of the city, the Lord Mayor has convened a meeting to be held in the Mansion House on Jan. 29th in "support of the claims of the Catholics of Ireland for equality in the matter of university education." The Very Rev. Dr. Delany, President of University College in the Catholic University of Ireland, has addressed a letter to the Lord Lieutenant of Ireland, protesting against any proposal that the claims of the Queen's College, Belfast, should be at once and separately dealt with, instead of being held over for consideration in connexion with a scheme for the reorganisation of the whole system of higher education in the country. Lord Dunraven has suggested a scheme which, it is said, was approved of on Jan. 12th by the Roman Catholic hierarchy at a meeting held in Maynooth. This plan is practically the one put forward by Sir Anthony MacDonnel and in brief is that two colleges should be affiliated to the present University of Dublin (with which Trinity College is connected)—viz., the Queen's College, Belfast, and a new Roman Catholic college, to be called the King's College, in Dublin on which a sum of £300,000 is reported to be spent. Something is also to be given to Trinity College, Dublin, and to Queen's College, Belfast. The scheme, whether the scheme of the Government or of Lord Dunraven, would seem still to be in an embryonic state and the religious difficulties to be adjusted are very grave. The announcement was made on Jan 18th that the board of Trinity College had received from His Majesty the King a letter authorising it to admit women to the degrees of the University of Dublin.

The Proposed Sanatorium for Consumptives at Whiteabbey.

A meeting of the inhabitants of Whiteabbey and surrounding districts was held in the court-house, Whiteabbey (the High Sheriff presiding), on Jan. 16th to protest against the purchase by the Belfast board of guardians of the "Abbey" for a sanatorium for consumptives. There was a very large and representative attendance. Objections were strongly urged against the scheme on the grounds of (1) injury to the neighbourhood and depreciation of property; (2) bad situation and site of the place selected, with a cold clay soil and adjacent swampy ground; (3) close proximity of a densely populated manufacturing village containing a spinning-mill; and (4) great cost caused by altering the present buildings and erecting huts, &c.

Jan 19th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Inspector-General of the Sanitary Service.

Dr. Chantemesse, professor of experimental and comparative pathology at the Faculty of Medicine, has just been appointed inspector-general of the Sanitary Service in the place of the late Professor Proust. No one has done more than the newly appointed inspector for the furthering of the science of hygiene and for prophylaxis against epidemic and contagious diseases. As scientific adviser to the Pasteur Institute Dr. Chantemesse has no equal among bacteriologists as regards scientific work, more especially in respect to typhoid fever. Moreover, the various sanitary missions with which he has been intrusted during past years single him out as one admirably fitted for the post to which he has just been appointed.

The Feeding of Infants.

At the Congress of Hygiene, which was held in Brussels in September, 1903, M. Budin laid down the principles which should regulate the feeding of infants. At the meeting of the Academy of Medicine held on Jan. 5th the same physician read a paper on the subject. Convinced of the dangers of over feeding, even when the infant is breast-fed, M. Budin laid stress upon the necessity for regulation of the infant's meals. The infant at the breast should be regularly weighed and the quantity of milk taken at each meal should be verified by weighing the child before and after sucking, if, that is to say, its increase in weight appears to vary. Gastro enteritis, which kills so many infants, is a [illegible] the quantity. [illegible] m the breast [illegible] ling is better [illegible] s to increase [illegible] to digestive troubles which impair nutrition and cause rapid wasting. Absolute bottle-feeding should not be thought of unless the mother has not even a trace of milk and of all the children who come to M. Budin's consultation rooms scarcely 5 per cent. are purely bottle fed. M. Budin has the greatest objection to this mode of feeding during the early months of life, for he considers it both difficult and dangerous, and although there are undoubtedly fine children reared in this way yet it cannot be said that they have run no risks. When the infant is some months old and weighs five or six kilogrammes a diet of exclusively sterilised cow's milk may be employed in quantities of 100 grammes per kilogramme of body weight, presuming that the milk is pure and contains 30 grammes of fat per litre. These are mean figures which may have to be modified by the medical man in accordance with the exigencies of any particular case. If the child be fed in this way and the results are not good the milk should be analysed and it will for almost a certainty be found that it has been either deprived of its cream or else watered. During the second year of life milk should still furnish the basis of the diet, but to it may be added some farinaceous foodstuff. Bouillon is useless and only slightly nutritive, one litre of bouillon not having the same nutritive value as 100 grammes of milk. Eggs are not advisable, especially for the poor who can rarely get them of good quality. On an exclusively milk diet or on one with a little farinaceous food added to it infants can be seen who at the age of two years weigh from 11 to 13 kilogrammes, with a daily ration of from 1000 to 1050 grammes of food. M. Budin's results, which he obtained together with his fellow worker M. Planchon, are particularly good. Out of 712 infants who were brought to him and whom he was able to follow up daily the mortality was only 4·6 per 1000, whereas the mean for all Paris is 178 per 1000. No infant died from digestive troubles, of which the mean official mortality is 65 per 1000. Both infectious and pulmonary complaints occurred in far lower proportion than in Paris as a whole, which argues a greatly increased resistance on the part of the infants under observation.

Abscess of the Maxillary Sinus.

At the same meeting of the Academy of Medicine M. Jarre read a paper dealing with the importance of the etiology of the disease in the treatment of abscess of the maxillary sinus. In the great majority of cases an abscess of this character has its origin in some dental trouble and not primarily in an inflammation of the mucous membrane lining the sinus. If the cause be removed a rapid cure generally follows and this removal may be brought about by one of the following measures: extraction or conservative treatment of a decayed tooth, extraction of a root left after attempted extraction of the whole tooth, extraction of an unerupted tooth, or extraction of the affected tooth with removal of any fragments of necrosed bone. The secondary affections of the maxillary sinus heal up after removal of the offending cause and it is but rarely necessary to interfere with the antrum of Highmore itself.

The Institute of Colonial Medicine.

The second session of the Institute of Colonial Medicine has just come to an end and M. Doumer has distributed the diplomas in colonial medicine to the students. The number of students on the roll during the past session was 45. Of these 25 passed the examination for a diploma but owing to lack of vacancies only 19 received it. Of these 25 students 12 were foreigners and 13 were Frenchmen. Nearly all were doctors of medicine and already occupied high posts in the navy, in the colonial army, or in the sanitary service of the colonies of different countries. M. Doumer, Governor-General of Indo-China, has granted to the institute a subvention of 30,000 francs per annum. At present the practical work and the lectures are carried on in the laboratories of the Faculty of Medicine but this is merely a provisional arrangement. Professor Blanchard has arranged with the Association des Dames Françaises that the institute should be able eventually to use as a hospital both for treatment and for clinical instruction the new hospital which the association is building at Auteuil. Professor Blanchard and Dr. Wurtz, the latter of whom is in charge of the instruction in medicine and colonial hygiene, have started for England at the invitation of the London School of Tropical Medicine, accompanied by 15 students. They bear with them as an offering to your distinguished parasitologist, Sir Patrick Manson, the honorary diploma of the Society of Tropical Medicine which was inaugurated on Dec. 1st, 1903, by the students and professors of the Institute of Colonial Medicine.

"Chloridated" Diet and Hyperchlorhydria.

At the meeting of the Society of Biology held on Jan. 8th M. Vincent gave an account of a case in which he had noted the influence of a "chloridated" or "non-chloridated" diet on the gastric chemical process. The case was that of a patient suffering from hyperchlorhydria and it was found that "chloridated" diet produced a series of disagreeable results, such as pains in the alimentary canal and even vomiting. When, however, the patient was put upon a diet freed from all chlorides so far as possible a marked improvement set in and the hyperchlorhydria diminished.

Jan. 19th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Serum Treatment of Scarlet Fever.

Professor Bókay of Budapest has given in the *Deutsche Medicinische Wochenschrift* an account of the treatment of scarlet fever by Moser's polyvalent antistreptococcic serum. He explains that out of 46 cases of scarlet fever 12 showing severe symptoms were selected for serum treatment, the amount injected being from 100 to 200 cubic centimetres. The result was that the general state of the patients, especially the cerebral symptoms, obviously improved in from 24 to 48 hours. The exanthem also was modified, for it either became paler or, if not yet fully developed at the time of the injection, it did not show itself profusely. The most striking effect of the serum, however, was the decrease of temperature, the fall ranging from 3·4° to 0·9° C. within 24 hours and in three cases the temperature even came down to normal. The pulse became less frequent and its quality improved. With respect to the other symptoms Professor Bókay agreed with Professor Escherich and Dr. Moser that when necrosis of the palate occurred it was less extensive and less deep than usual; well marked nephritis and arthritis developed twice in a mild form; adenitis developed in four patients, of whom two died from septic pyæmia, these being the only fatal cases. Otitis developed, too, in several cases but only in a mild form. As to undesirable complications Professor Bókay mentions that there was one instance of suppuration at the place of the injection which healed after an incision had been made. Transitory albuminuria was once observed; albuminuria existing already at the time of the injection did not increase and sometimes even disappeared. An eruption attributable to the injection developed in seven cases—i.e., in 58 per cent. of the patients, whereas this symptom was observed by Dr. Moser in 75 per cent. It usually appeared between the sixth and sixteenth day but was once as late as the fourth week; it took either the form of urticaria or of erythema multiforme or was like the eruption of rubeola and scarlet fever. Professor Bókay concludes from his observations that Moser's serum has a specific antitoxic action against scarlet fever and that the results of the treatment are satisfactory but that further experience is indispensable previously to its introduction into general practice.

The late Professor Jolly.

Dr. Jolly, professor of psychiatry at the University of Berlin and chief of the university clinic for mental and nervous diseases, died suddenly on Jan. 3rd. He was born at Heidelberg in 1844. He came of a prominent Baden family, several members of which distinguished themselves in public and academical life. His father was a professor of physics at the Universities of Heidelberg and Munich; his uncle served the Government of Baden in a political capacity and had duties to perform in connexion with the revival of the German Empire in 1870 Professor Jolly received his professional education in Munich and Göttingen, where he obtained his medical qualifications in 1868, and then became an assistant in the medical clinic at Munich under Professor Pfeufer. After a time he left this place for an appointment at the lunatic asylum of Werneck under the celebrated Professor Gudden who, as is generally known, lost his life in tragic circumstances, together with the late King Ludwig of Bavaria. Afterwards he became an assistant to Professor Rinecker at Würzburg, where he was recognised *privat-docent* in 1872. When Professor Krafft-Ebing left Strasburg for Vienna in 1873 Dr. Jolly was called to take the chair of psychiatry at the former university which he quitted only 1890 to succeed Professor Westpfahl as ordinary professor mental diseases at the University of Berlin. His published work was on the subject of the Cerebral and the Circulation in the Brain. At a later he contributed the chapters on Hysteria and H to Ziemssen's "Handbook of Clinical Medicine" a series of essays on different psychiatric questions the *Archives of Psychiatry*, *Charité Annals*, and o periodicals. Recently he devoted much attention to the reconstruction of the Royal university clinic for mental and nervous diseases, an institution which seems destined to become a model of its kind. A sudden death from rupture of an aneurysm of the aorta has, however, prevented him from seeing the completion of this work. Professor Jolly was president of the German Psychiatric Association and of the Berlin Psychiatric Society; he was very highly esteemed by the profession and by the public, so that the news of his death has been received with general regret.

Death of Dr. Dettweiler.

The death of Dr. Dettweiler, late chief physician to the Falkenstein sanatorium for consumptives, is announced. The deceased, who was one of the earliest and most successful advocates of the open-air treatment of tuberculosis, was born in 1837 at Wintersheim in Hesse. On receiving his medical qualification in 1863 he entered the army medical service and took part in the wars of 1864, 1866, and 1871, after which he proceeded to Görbersdorf to join the late Dr. Brehmer, the founder of the first sanatorium for consumptives in Germany. They worked together for six years, at the expiry of which Dr. Dettweiler left Dr. Brehmer and founded a new sanatorium at Falkenstein, near Kronberg in the Taunus Mountains. Whilst Dr. Brehmer laid great stress on the elevated position of his sanatorium and on the value of systematic walking exercise in strengthening the heart muscle the principal features of Dr. Dettweiler's method at Falkenstein were the so-called "Liegekur" and dietetic treatment. One of his greatest merits was the foundation of a sanatorium for the indigent classes as early as 1891, at a time when none but the wealthy enjoyed the benefits of this special treatment. Both in national and international congresses and in numerous publications he pleaded for the hygienic treatment of tuberculosis and it was principally due to his influence that the movement for providing sanatoriums for the poorer classes has been so successfully developed in Germany. Dr. Dettweiler retired from practice a year ago on account of the state of his health. The Falkenstein sanatorium, so well known both in Germany and abroad, and specially in England, has since that time been, and will continue to be, conducted according to the principles followed by its founder.

Statistics of the University of Berlin.

The number of students at the University of Berlin is higher just now than at any time since its foundation in 1810. According to the daily press there are 7503 matriculated students [illegible] ·ological, 2565 to the [illegible] 1193 to the medical [illegible] medical students fortunately shows a slight decrease. It is interesting to observe the increasing number of foreigners, of whom no less than 1184 are registered, being nearly one-sixth of the students. As regards numbers the Russians head the list, of which nationality there are 440; then of the other European nationalities there come 136 Austrians, 93 Swiss, 55 Hungarians, 46 British, 36 Roumanians, 23 Servians, 22 Italians, 21 French, 20 Greek, 18 Bulgarians, 15 Scandinavians, 14 Luxemburgers, 11 Dutchmen, 10 Spaniards, 8 Turks, 7 Danes, 3 Belgians, and 2 Portuguese. Of students from other countries 160 come from America, 40 from Asia, 3 from Africa, and 1 from Australia The regulations of the University do not allow females to matriculate but 532 women are nevertheless admitted to the lectures. The Army Medical Academy, which is to some extent in connexion with the medical faculty of the University, has 318 students.

Medicine and the Law.

A man who was suffering from gonorrhœa and syphilis was recently brought before a law court in Munich on a charge of infecting a young woman by cohabitation. He had been informed by his medical attendant as to the nature of his ailment and warned against cohabitation and on this ground he was found guilty of having caused bodily injury by neg[illegible] sentence [illegible] parison [illegible] hoped th[illegible] kind, th[illegible] brought [illegible] a law court in Germany. Another judgment, also of medical interest, had reference to a man who was prosecuted for having caused the death of his daughter by neglect. The child suffered from suppuration of the knee-joint and the surgeon in attendance declaring an operation to be urgent advised the father to take her to a hospital. The child, however, implored him to leave her at home, which he accordingly did. On her death, which was due to pyæmia, the father was found guilty by the local court but on appeal he was acquitted by the Supreme Court which decided that he had acted excusably in complying with the wishes of the patient.

Jan. 18th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Sanitary Improvements in Cairo.

THE first serious attempt at improving the sanitary arrangements of Cairo has just been made by the Savoy Hotel. This is the adoption of the septic tank system for the disposal of sewage in place of the unpleasant cesspit which has for so long been considered the acme of perfection in sanitation in Egypt. The whole plant, which is most solidly built in Hennèbique cement, stands in the grounds behind the hotel at the base of the V formed by the diverging wings of the building. The general arrangement of the system adopted is as follows. The pipes which carry the waste from the kitchen, laundry, and baths join with those from the water-closets and urinals and with the waste pipes from other parts of the building in one large drain at the entrance of the collecting pits. All the waste water and sewage are in this way passed directly into two deep cement pits and thence into a set of smaller pits or grease traps in which all the grease and oily matters generally are collected and removed. The residue passes on again into a large underground cement tank which is capable of holding a 24 hours' supply and is very dark and tightly closed. Here, as the manager of the hotel quaintly but correctly puts it, the microbes do their work. After a sufficient time has elapsed for all the bacterial processes to take place the fluid contents of the tank are led off by way of pipes, opening below the level of the surface of the sewage, straight on to a large filter bed (seven metres thick and more) consisting of alternating layers of stone, sand, and coke, and filters into the old, now disused, cesspits, from which it may be pumped and used for the garden, or it is allowed to percolate through the soil beneath the filter-bed into the subsoil water, which is particularly plentiful in Cairo in such close proximity to the Nile. A varying amount of semi solid matter remains in the septic tank and this must be removed at long intervals. There is really no danger to be feared from sewage treated in this way provided that no escape of gas is permitted and that the effluent easily reaches the subsoil water and is thus carried away. Sufficient time must be allowed for thorough disintegration to occur and the sewage must therefore be slowly let into the tank from the collecting pits, the rate of inflow varying with the rapidity of the bacterial action. The whole installation is arranged in a comparatively small space, but the first cost is considerable, the present plant requiring nearly £700 to complete. It says a great deal for the management of the Savoy Hotel that so soon after putting in an elaborate system of cesspits they should have gone to such an expense in adopting a better method of sewage disposal as soon as experience demonstrated the unsatisfactory working of the former system. That this is not the only direction in which the Savoy Hotel caters for the comfort and well-being of its visitors is evident from the fact that a new system of electric heating has just been completed throughout the hotel. It is gratifying to know also that the Standard Life Insurance Company, which is about to build a large block of buildings quite close to the Savoy Hotel, conditional on the success of the present scheme, intends to adopt the same system in preference to the more antiquated and unsavoury methods hitherto in vogue in Cairo.

The New Italian Hospital.

The various foreign nations in Egypt have during the last few years begun to realise their obligations towards their rapidly increasing colonies and have built hospitals in which their people may be treated by medical men of their own nationality and be nursed by their fellow countrywomen. It is to be admitted that the British colony, numerically a small one it is true, has been about the last of all to awaken in this respect and the new Anglo American hospital, which is shortly to be opened, is the result. There are now in Cairo, in addition to others on a less pretentious scale, a French hospital, a German, an Austrian, an Anglo-American, and now an Italian has just been opened. By the kindness of Dr. Tonin, the physician to the hospital, and of Dr. Gaglio, who is in surgical charge as well as being resident medical officer, I had an opportunity of inspecting the building on the day before that on which the patients were admitted. The King of Italy has contributed largely to the building fund and the Italian community in Cairo—numbering in all some 16 000 persons—has very generously assisted. At the present time accommodation is provided for 50 patients but there is ample space for further buildings as funds become available The hospital is a distinctly impressive building situated at Abbassieh, well away from the main road and on the fringe of the desert between it and the Mokattam hills. It is built in pavilions all connected together by covered passages. The front block, which is parallel to the road, contains the administrative offices, special wards for paying patients and serious operations, and the operating theatre. In the latter all the most practical aseptic arrangements are made and the whole set of rooms, consisting of a small anæsthetic room, the theatre proper, and the sterilising room beyond, is coated throughout with a splendid enamelled surface which can be washed down periodically by means of a small hydrant that can be attached to a hot-water plug in a hidden recess in the wall. One was particularly struck with the perfectly plain flat doors which when closed were quite flush with the walls and the absence of all ledges liable to collect dust, and also with a particularly good washing basin with pedal action one of Shanks' latest In the upper floor of this block are the resident's quarters with a lovely view of Cairo and the desert. The air is beautifully clear and dry and a better site for a hospital could hardly be imagined. The general wards are in two separate blocks, connected with the front by covered ways and consisting for the present of only one floor. In each block are several small wards for special cases and a large ward of 14 beds beyond, which is sure to be always well filled, as the hospital is intended primarily for poor Italians who are entirely unable to pay anything for their hospital treatment. Separate buildings are provided for the kitchen, the laundry, and the mortuary, which latter is finished in enamel composition to facilitate cleaning and washing. With the very large Italian colony in Cairo it may be confidently anticipated that this hospital will prove a very great boon to its suffering poor and it is reasonable to expect that further additions will be required in the near future. It was found that after the French hospital had been opened a year it had to be enlarged to twice its original extent to accommodate the many applicants for admission. This augurs well for both of the new hospitals, the Italian and the Anglo-American of which I hope to be able to chronicle the opening very soon.

Cattle Plague.

Hardly anything could be more expressive of the danger to be anticipated in connexion with the recrudescence of cattle plague in Egypt than the last bulletin of the Director-General of the Sanitary Department. It states that during the week ending Dec. 20th, 1903, there were 2234 deaths from "bovine typhus" reported throughout the country. Of these 1983 occurred in Upper Egypt and there was an increase of 752 over the number for the preceding week The total number of deaths which have occurred since the commencement of the epidemic amounts to 13.462 The Director-General complains in emphatic terms that owners of cattle not only do not give assistance to the sanitary administration in the efforts which the latter is making to wipe out the disease, but that they even do their utmost to conceal the disease and to deceive the agents of the administration in their inspection of villages. He makes no objection to sick animals being slaughtered and their flesh sold for food but he regrets that the hides of these animals are also sold, as they spread the disease when taken from place to place by the purchasers.

Jan. 10th.

Obituary.

FRANKLEN GEORGE EVANS, M.R.C.S. Eng., L S A.

Mr. Franklen George Evans, who died on Jan. 17th after an attack of apoplexy, had given up general practice for more than 20 years but he was so closely identified with many large undertakings in the Cardiff district that his death will be regarded as a distinct loss to the community. Mr. Evans, who was born in Cardiff in 1827, was the son of Edward Evans, at one time the only surgeon in Cardiff for in 1821 the population of the borough was less than 3500. Mr. Franklen Evans received his medical education at St Bartholomew's Hospital and in 1849 qualified as M.R.C.S. Eng. and L S A. After being house surgeon to the Cardiff Infirmary, or as it was then styled, the Glamorgan and Monmouthshire Infirmary and Dispensary, he was appointed surgeon to the Pentyrch Colliery and Ironworks and to the Melingriffith Tinplate Works, holding this position until 1878, when the colliery and ironworks were closed. Mr. Evans was at the time of his death chairman of the Rhymney Railway Company and a director of the Pontypridd Waterworks Company as well as of many other large industrial concerns. He was very much attached to the study of astronomy and was a Fellow of the Royal Astronomical Society. A few years ago he presented to the Cardiff corporation a large and valuable astronomical telescope Mr. Evans was twice married, his second wife being a grand-niece of Mrs. Wyndham Lewis who subsequently became the Countess of Beaconsfield.

Deaths of Eminent Foreign Medical Men.—The deaths of the following eminent foreign medical men are announced:—Professor Karl Gebhard, a well-known teacher of gynæcology in Berlin. His death followed an operation.—Dr. Ewald Wolff of Breslau, at the age of 88 years. In early professional life he was distinguished as an operator in cases of strabismus. Later he was appointed to high administrative rank and wrote on many subjects connected with State medicine.—Dr Georg Freiherr von Liebig a son of the celebrated chemist, at the age of 76 years. He possessed an English qualification and was for a time in the East India Company's service. He also acted as professor of natural history in Calcutta. After the Mutiny he returned to Germany and was for many years *privat-docent* of climatic medicine in the University of Munich.—Dr. Emile Leidié, professor of chemistry and toxicology in the Ecole Supérieure de Pharmacie in Paris.—Dr. Karl Emmert, professor of State medicine and senior member of the medical faculty of Berne, at the age of 91 years.—Dr. Ryher, formerly lecturer on clinical medicine in the University of Dorpat, at the age of 72 years.—Dr. Theodor von Schröder, editor of the *St. Petersburger Medicinische Wochenschrift*.—Dr. S. Verekundoff, *privat docent* of the history of medicine in the Military Medical Academy of St. Petersburg.

Medical News.

University of Cambridge.—Graduates in Arts of the University of King's College, Windsor, Nova Scotia, are to be admitted to the privileges of affiliated students of the University of Cambridge. At the Congregation on Jan. 14th the following degrees were conferred:—

M.B.—T. Guthrie, King's.
B C.—N. C. Carver, King's; H. A. Clarke, Trinity; H. D. Hoffmann, Trinity; J. E Pellow, St. John's; C M. Murray, Pembroke; G. E. Davidson, J. H Donnell, and E Gardner, Caius; P. Hardy, Trinity Hall; and E. Higson, Magdalene.

Foreign University Intelligence.—*Bonn*: Dr. Fischer has been recognised as *privat docent* of Pathological Anatomy.—*Copenhagen*: Dr. V. Rubow has been recognised as *privat docent* of Medicine and Dr. V. Jensen as *privat docent* of Bacteriology.—*Erlangen*: Dr. Robert Heinz, *privat docent* of Pharmacology, has been promoted to an Extraordinary Professorship. He has also been appointed to the charge of the Pharmacological Institute.—

Freiburg: Dr. K. Schleip has be
docent of Medicine.—*Halle:* Dr.
been offered the chair of Mental
Heiorenner is obliged to resign on account of the state of his health.—*Kiel:* Dr. Hans Nösske has been recognised as *privat docent* of Surgery.—*Munich:* Dr. Seitz has been appointed chief physician to the Gynæcological Clinic.—*Naples:* Dr. Giuseppe A. Petrone has been recognised as *privat-docent* of Pediatry.—*Pavia:* Dr. Luigi Devoto, Extraordinary Professor of Internal Pathology, has been promoted to be Ordinary Professor.—*Salamanca:* Dr. Arturo Nuñez y Garcia has be
burg: Dr. F.
Professor of
been recognised as *privat docent* of Midwifery and Gynæcology.—*Vienna:* The selections for the Dermatological chair of the late Professor Neumann are: (1) Professor Rille of Leipsic, (2) Professor Anton Mracek, and (3) Professor Maximilian von Zeissel. Dr. Leopold Harmer has been recognised as *privat-docent* of Laryngology.—*Würzburg:* Dr Dieudonné, *privat-docent* of Hygiene, has been appointed Professor. Dr. Josef Arneth has been recognised as *privat-docent* of Internal Medicine.

DONATIONS AND BEQUESTS.—Sir W. T. Lewis, the president of the Hamadryad Seamen's Hospital, Cardiff, has given £1000 for the endowment of a bed in memory of the late Lady Lewis.—The Clothworkers' Company has voted £1000 payable in five yearly instalments of £200, to King's College Hospital Removal Fund.—The employés of Messrs. J. S Fry and Sons, Limited, have contributed £617, and the workpeople of the Imperial Tobacco Company £500, to the Bristol medical charities.

LITERARY INTELLIGENCE.—A volume, announced by Messrs. J. and A. Churchill, is just ready for publication and comprises the second series of lectures on Diseases of the Nervous System, by Sir William R Gowers, F.R S The lectures, which are ten in number, deal with the following subjects: Subjective Visual Sensations; Subjective Sensations of Sound; Abiotrophy: Diseases from Defects of Life; Myopathy and a Distal Form; Metallic Poisoning; Syphilitic Diseases of the Nervous System; Inevitable Failure; Syringal Hæmorrhage into the Spinal Cord; Myasthenia and Ophthalmoplegia; and the Use of Drugs. They have been carefully revised by the author for publication in this form.

LECTURES IN MEDICAL JURISPRUDENCE.—On Jan. 14th Dr. F. J. Waldo, coroner for the City of London, delivered the first of a series of six lectures on medical jurisprudence at the Old Hall, Lincoln's Inn, under the auspices of the Council of Legal Education. The subject of the first lecture was the Medical Man as Witness. At the
disabilities attached to the registra-
ere dealt with. A medical man might
a common witness to facts or as an
leduction and experience. The why
and wherefore of conflicting medical evidence were next
and reasons were given to show
could contradict each other in
onesty. The illustration of this
railway spine," cases of accidental injury in which the widest difference of opinion often prevailed. The ending of litigation was often attended by a speedy recovery on the part of the patient Quite as great or greater differences existed among lawyers, as proved by the reversal of decisions, time after time, in successive courts, until the House of Lords
question of profe important
able length and consider-
nt appeal
of a provincial head constable to the local medical men for information likely to identify the offender in a case of infanticide. A medical witness is bound to answer fully in the witness box if required to do so by the court, except where by so doing he would incriminate himself. In ordinary life, however, any violation of professional secrets might involve an action at law. The unwritten law of the medical profession appeared to be that there was no obligation to reveal anything that came under their notice short of murder or the very gravest criminal charges. This professional secrecy dated from the earliest times, as shown by the oath of Hippocrates, the substance of which was still adopted in the declaration of the Scotch medical graduate The lecturer concluded with an analysis of the various kinds of medical evidence and some of the points concerned in the medical examination of prisoners.

GUY'S HOSPITAL.—On Jan. 19th a concert in aid of the funds of Guy's Hospital was given in the public Hall, Eltham, by the Toy Orchestral Society of that place. Two toy symphonies were given, one being by Gurlitt and the other by Desmond Ryan. Songs, violin solos, and musical sketches were contributed by Mr. N H. Cox, Mrs. Reynolds, Mrs. Worthington, and Mr. Tom Clare. The concert was a great success and the sum of £28 will be handed over to the charity as a result.

WEATHER AT SEVENOAKS IN 1903.—We have received an interesting printed report of the weather at

years, nearly 34 inches, is now made up, the rainfall of Sevenoaks greatly exceeding that of London. The rain at night time was in the proportion of two to one more than during the day.

THE COLONIAL NURSING ASSOCIATION.—The Goldsmiths' Company has forwarded £50 and the Mercers' Company 10 guineas, in addition to sums from other contributors, to the Colonial Nursing Association. The association has since its foundation in 1896 supplied nearly 200 nurses for work in the Crown colonies and in other British communities abroad. At the present time 105 nurses are at work in various parts of the empire and many applications are being received for nurses in all directions from new districts in India, the Transvaal, and East Africa. Subscriptions may be sent to the honorary secretary, Colonial Nursing Association, Imperial Institute, London, S.W., from whom all particulars may be obtained.

SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—A meeting of the council of this society was held at 20, Brunswick-square, London, W.C., on Jan. 12th, Mr. Joseph Smith being in the chair. The following resolutions were unanimously agreed to and ordered to be sent to the College:—

1. That this council considers the reply of the College Council to the
Fellows and Members
repeated refusal to
n meetings to which
ouncil emphatically
esent the Members,
its efforts to obtain
the body corporate.

It is stated to be the intention of the society to hold meetings of Members in various provincial centres during the year in order to protest against their continued exclusion from all collegiate rights.

BOOKS, ETC., RECEIVED.

Hinds.—On Jan 13th, at Tennyson-road, Worthing, the wife of Fras Hinds, M.D., of a son.

May.—On Jan. 20th, at Ivanhoe, 50, Archers-road, Southampton, the wife of Henry J. May, M.B., B.C. Cantab., of a daughter.

Newton.—On the 13th instant, at *Brookhill, Sheffield*, the wife of Duncan Gray Newton, M.B., C.M., of a daughter.

Williams.—On the 19th inst., at Bryn Derw, Penarth, the wife of W. Williams, M.A., M.D., County Medical Officer, of a son

MARRIAGE.

Swales—Pentin.—On Jan. 20th, at St. James' Church, West Derby, Liverpool, by the Rev. G. Fred Wills, vicar of Up-Holland, near Wigan, Edward Swales, M R.C.S., L.R.C.P. Lond., to Florence Booth, third daughter of the late F. J. Pentin, of Liverpool.

DEATHS.

Barry.—On Jan. 14th, at the residence of his uncle, Alfred Palmer, Esq., J.P., Wokefield-park, Mortimer, Gerald Exall, the beloved and only son of Mrs. Barry, 3, Nevern-square, S.W., and of the late Dr. F. W. Barry, of H.M. Local Government Board.

Longden.—On the 18th inst., at Kempe-road, Kensal-rise, Duncan Campbell Longden, F.R.C.S. Ed., aged 37.

Turner.—On Jan. 2nd, 1904, at his residence, 197, Walm-lane, Cricklewood, N.W., Alfred James Turner, M.D., aged 58 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE PREVALENCE OF QUACKERY.

WE have received a little handbill entitled "The Health Guide," which bears on its front page the names of Messrs. "Constantine and Jackson," with their address and the statement that they are the sole agents in England for Dr. Henry Paterson. The bill goes on to state that Dr. Paterson, who, we suspect, is an American product, has made "marvellous medical discoveries" which "radically cure most chronic diseases from whatever cause arising." We learn also that at a depôt near the Law Courts, London, "those afflicted with skin, blood, and nervous disorders may rely upon obtaining sound scientific and conscientious treatment." We are also asked to note that "all consultations concerning various complaints of men and women are absolutely free," that "a specialist attends daily," that "Dr. Paterson's Soluble Sandal Oil and Copaiba Capsules are prepared with the greatest care," that "all kinds of surgical instruments and rubber goods are kept in stock," and that "analyses are undertaken." The handbill is addressed "To the Editors of THE LANCET, Quack Department."

We wish that it were possible for us to have a bureau attached to this office where the rapacity and mendacity of quacks could be systematically exposed. We feel, however, that we can only touch upon the fringe of this enormous subject. Dupes demand to be swindled all the world over, while it is but human nature that unfortunate sick people, failing from the very nature of their diseases to find relief in scientific medicine, should have recourse to the ministrations of the charlatan. The demand thus created for quacks is stimulated by the venality of newspaper proprietors who accept disgusting and disgraceful advertisements from persons of well-established roguery, careless of the harm that may thus be done to the health and the pockets of their *clientèle*. Only a few years ago column after column of newspapers, the proprietors of which would certainly have been annoyed if they were told that their journalistic enterprise was not respectable, teemed with the advertisements of abortion-mongers. The abuse became so grave that we directed close attention to it and in a short series of articles were able to show that the "female remedies" and "medicines to cure all obstructions" offered to women at high prices presented the following features: (1) they were intended to be used by women for the purposes of criminal abortion; (2) they were in some cases actively mischievous in the direction intended; (3) they were in many more cases inert, the woman merely having been swindled out of her money instead of having been abetted in her intended crime; and (4) their price was completely extortionate, sums ranging from 5*s.* to £5 being demanded for medicine that would have been dear at five farthings. As a result of our articles respectable papers refused advertisements of the sort that we indicated as criminal or fraudulent and the infamous trade came practically to an end. Against definite groups of quack remedies of this sort definite action can be taken, but with regard to quackery in general we can only make the general remark that its increasing prevalence forms a poor comment upon the intelligence of the people and a queer sidelight upon commercial morality.

ICHTHYOL IN BONE DISEASES.

To the Editors of THE LANCET.

SIRS,—Could any of your readers give me any information dealing with the effect of ichthyol on chronic bone diseases or refer me to any literature on the subject?—I am, Sirs, yours faithfully,

Jan. 18th, 1904. JUNIOR PRACTITIONER.

"SO HERE I AM FOR FIGHT."

THIS heading aptly describes the proceedings of both sections at a recent meeting of the North Dublin board of guardians, where questions of some medical importance were ventilated. On Jan. 7th a very unseemly discussion took place at a weekly meeting of the North Dublin guardians with reference to the action of the visiting surgeon to the North Dublin Union Hospital. It appears that a refractory patient at the union who, according to Mr. Caleb J. Powell, the surgeon in question, "committed the most filthy nuisance in the ward where there were other patients, some of them dying," and who "on more than one occasion assaulted the attendants," was ordered to be removed to the lunatic infirmary. Whereupon a section of the guardians appear, by the account in the *Dublin Express*, to have charged Mr. Powell with having exceeded his duty, it being said that no complaints had been made against the patient in question by the attendants. This, however, was shown to be false and one of the guardians said that attempts had been made to injure Mr. Powell on several occasions during the past six or seven years. Expressions such as "a cad," "hunt him down," and "make him sit up" were said to have been used by female guardians with reference to Mr. Powell. These allegations were denied by the women implicated and the approval by the board of guardians of Mr. Powell's action was entered on the minutes. The whole tone of the proceedings showed that a proportion of the guardians present looked upon the meeting as an opportunity for the exercise of pugnacious proclivities. A speaker, who had a green patch over one of his eyes (we learn this from our contemporary's picturesque account) read the following stanza in support of Mr. Powell:—

> "I hope you will excuse me all,
> As I have got an ugly fall;
> The just man falls seven times a day—
> Then how could I escape, I pray?
> I fell 'gainst will a rough curbstone,
> I slipped my foot, and down was thrown;
> A little blood no doubt was sped—
> But still the green's above the red;
> So here I am for fight, 'tis true,
> The Faugha Balla! whack, hurroo!'

Immediately afterwards some one called a brother guardian "a bigoted Papist," and a female guardian objected to the statement that she was "no lady." Ireland is not the only country where a board of guardians has been found to misbehave, but we think that such a meeting as the one to which we have been alluding could hardly have taken place anywhere except in Ireland. The regrettable religious question gets mixed up with public affairs and thus any official, however capable or honourable, runs a chance of being vilified by opponents whose attitude is dictated by their creed and not by their judgment.

AN INLAND HEALTH RESORT.

To the Editors of THE LANCET.

SIRS,—Can any of your readers kindly inform me, a medical man, which is the best health resort in England during the spring in order to escape the early winds. An inland place would be preferred and it should not be relaxing Is there any better place than Clifton?

I am, Sirs, yours faithfully,

INQUIRER

HIDDEN TREASURE.

SOME little time ago we suggested that the perpetual digging up of the roads and footpaths might be due to the fact that the diggers, or the authorities on whose directions they acted, imagined that hidden treasure existed. Our hypothesis, which was at the time received without the gravity due to it, has to some extent become realised. For parts of London are now infested with excavators who are avowedly searching for money. A Sunday newspaper, as many of us have reason to know, recently issued advertisements to the effect that tokens to the value of £50 were buried in certain districts of the metropolis, which districts became thereupon infested with roughs intent on digging through or into anything in their quest of loot At Marylebone police-court on Jan. 18th a labourer was sentenced to a fine of 40*s.* or one month's imprisonment for damaging the roots of a tree in Maida Vale, the property of the borough council. At Clerkenwell police court on the same day four other persons were charged with damaging property while hunting for the treasure. Evidence was given at both courts of widespread damage but at Clerkenwell the magistrate took the defendants' bail for their good behaviour. Mr. Debenham, who prosecuted at this court, said very rightly that the persons really responsible were the proprietors of the newspaper, but Mr. Bros pointed out that he did not see his way to issue any process against them. The law, as we know on very good authority, "is a ass, a idiot,' but surely some way could be found of bringing to justice persons who are no more or less than inciters of others to commit illegal acts. Action can be taken against the dupes of the paper for trespass and damage but the real offenders go unpunished. The proprietors of the paper in question may think themselves fortunate that they do not live in the Western States of America for there they would probably receive the sentence of lynch law from outraged private citizens. It is difficult to bear with equanimity the mining operations of our municipalities; there is no need to be patient at all in the matter of these treasure-seekers.

OLD LAMBETH.

THE January issue of the *St. Thomas's Hospital Gazette* contains an interesting article on the excavations being made for the erection of a nurses' home at St. Thomas's Hospital Two coloured prints accompany the article. One is a reproduction from a mezzotint dated 1795 which shows the palace, Bishops' Walk, and some small houses on the river bank. The other shows the north end of Bishops' Walk with the small houses on the west side of the road and the wall of the palace garden opposite Bishops' Walk was a beautiful promenade lying between the Archbishop's garden and the river. It was swept away to make room for the Albert Embankment. In early times Lambeth was part of the great marsh on the south side of the river and was submerged by the stream at each high tide. On the opposite side of the river was the Isle of Thorney, now Westminster, through which all the trade of the north passed on its way to Dover or to the south coast. The merchants crossed the river by ford or by ferry—the name of Horseferry-road commemorates th [illegible] was a Royal house where it is said [illegible] after a drinking bout or, as Sir [illegible] rom a blow received while engaged in the dangerous sport of bone-throwing. This Royal house was at one time the home of the Black Prince and his son Richard II. In the sixteenth century and onwards Lambeth fields were the favourite resort of Londoners and the place was celebrated for the variety of sweet-smelling flowers and medicinal herbs which grew there. In the reign of William III., where now is Lambeth-walk, there was a celebrated place of amusement called Lambeth Wells, and its waters were held in high repute; they were advertised at "a penny a quart, the same price paid by St. Thomas's Hospital." Searle's boat house, which is to be seen in the second of the two prints, was quite familiar to boating men of 40 years ago, and here the boys of Westminster School kept their boats. About the time when it was demolished one of the boys being given the quotation, "*Non sors sed fors sua cuique loco est,*" upon which to write an epigram produced the following:—

> "Searle's boat-yard's taken from us
> And embankments *sore* provoke us,
> We've no *locus* for our boat house,
> Where we used to keep our *Fours.*
> If the poet truly tell us
> There's a *fors* for every *locus*,
> Then doubly hard on us 'tis
> We've no *locus* for our *Fours*,
> While to Searle's yard succeeding
> By a slightly different reading
> The patients of St. Thomas
> Find a *locus* for their *sores.*"

The writer concludes his article by saying that, "Probably before very long Lambeth, as we know it at present, will be only a memory; we shall find it then as hard to reconstruct the Lambeth of to-day as now we find it to form any real picture of Lambeth before St. Thomas's migrated."

MUGNA'S SMOKE-WASHING APPARATUS.

MR. L. BARNABÈ of 12, North-crescent, Tottenham-court-road, London, W., has drawn our attention to the application of this smoke-washing apparatus to two chimneys at a restaurant in the Strand where it may be seen daily in action. The apparatus was described in THE LANCET of March 21st, 1903. It consists of a fan which sucks the smoke from the chimney into a chamber fitted with revolving paddles which bring the smoke into intimate contact with water. The effect is excellent. Instead of black smoke pouring out of the chimney, as was previously the case, there is now only a slight discharge of white and practically odourless vapour. Both the fan and the paddle are revolved by means of a small dynamo, the whole arrangement being on the roof. The effectiveness of this appliance is very obvious from the filthy condition of the wash-water. The apparatus serves also to accelerate the draught up the chimney, while it effectually prevents the down draught. This is a very important consummation where kitchens on the top floor are concerned. We have often pointed out that it is the chimneys of hotel and restaurant kitchens which contribute largely to the foul smoky state of the atmosphere of London. It is stated that this apparatus is economical in use and the soot and tarry matter which accumulate in the tank may be used as fuel or for other useful purposes.

DANIEL LAMBERT.

To the Editors of THE LANCET.

SIRS,—In regard to your references to Daniel Lambert and Edward Bright in your annotation "The Fat Boy of Peckham" in THE LANCET of Jan. 9th, 1904, perhaps the following note which I have discovered in the *Monthly Magazine* of July, 1804, may be of interest to your readers:—

> "One of the greatest prodigies at present in this kingdom, if not an extravagation of nature, is Mr. Samuel (*sic*) Lambert of Leicester, and master of the county jail there, who weighs not less than 45 stone 12 pounds, which is about half a hundred-weight more than what the famous Bright of Malden weighed, who, as appears from authentic testimonies, could button seven men within his waistcoat. Mr. Lambert had often objected to being weighed, but getting into a postchaise by a preconcerted plan of some of his friends he was taken over a weighing machine where it was ascertained with great facility to his no small mortification."

All the Year Round of August 25th, 1860, stated that when Daniel Lambert died he weighed 53 stones. In conclusion, I believe that a certain Mr. Joe Grimes of Cincinnati, U.S.A., claims to be the largest man in the world. He is 6 feet 4 inches in height and weighs 54 stones.

I am, Sirs, yours faithfully,

Jan. 18th, 1904. S. B.

◆

Ismail.—We are only in a position to advise our correspondent very generally. In the working of the suggested new and joint practice there will be two things influencing the shares of profits: (1) the prestige of the medical men and (2) the amount of work done by each. It is clear that the older firm will enter upon the new practice with excellent introductions, so that they may fairly attribute some of the earlier patients as coming to them, their names being well known. On the other hand, it is possible that the gentleman with the smaller practice will have more time to devote to the new work. Supposing that the junior partner in the old firm and the prac tioner with the smaller practice did the new work equally betwe them then the profits might be divided into three shares, one-thi going to each of the two men doing the work and one-third for certain period of time to the older firm in return for the introducti afforded by its name. It would be well to instruct a solicitor to p this or some such agreement on paper when the details could settled by friendly argument between the parties concerned. T idea of amalgamation is a good one.

A. F.—Gardiner's "Household Medicine and Sickroom Guide," ed by W. H. C. Staveley, F.R.C.S., thirteenth edition; London, Smit Elder, and Co., 1898, price 8s. 6d. "Practical Nursing," by I Stewart and H. Cuff, M.D. Lond., will also be found useful. T work is in two volumes and is published by William Blackwood a Sons, London and Edinburgh. Our correspondent might also apply to the St. John Ambulance Association, St. John's Gate, Clerken-well, London, E.C., for their "Manual of First Aid."

Ex-civil Surgeon (late Boer war, now in private practice) asks:—On what occasions can I with good taste wear the South African medal? Can it be worn when in evening dress at public dinners, functions, &c.; should the medal or only the ribbon be worn?

Urgent should consult his solicitor as to the proceedings to be taken under what is termed a Deed Poll.

EDITORIAL NOTICES.

IT is most important that communications relating to the ditorial business of THE LANCET should be addressed clusively "TO THE EDITORS," and not in any case to any ntleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1903, which was completed with the issue of Dec. 26th, were given in THE LANCET of Jan. 2nd, 1904.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1903 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

note that only those subscriptions
he Proprietors of THE LANCET
W.C., are dealt with by them!
on or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "*London* and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

A Clinical Lecture
ON
HYSTERICAL SKIN SYMPTOMS AND ERUPTIONS.

Delivered at the West-End Hospital for Diseases of the Nervous System,

BY THOMAS D. SAVILL, M.D. LOND.,
PHYSICIAN TO THE WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM AND TO THE ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

GENTLEMEN,—The skin symptoms of hysteria, other than sensory changes, with which I do not propose to deal on the present occasion, have not attracted the attention they deserve. They are, however, of great importance, first, because we can very often see them for ourselves in a manner which cannot be done in many of the other symptoms of hysteria; and, secondly, these same lesions which we see upon the surface of the body may, as I pointed out on a previous occasion, also take place in the central nervous system and other parts in the interior of the body and produce many and various hysterical symptoms according to the part involved. I have met with seven different kinds of [illegible] algia; (6) urticarial, erythematous, and hæmorrhagic exudations; and (7) localised ischæmia. The first three are quite peculiar to the emotional vaso-motor neurosis, as I regard it, which we call hysteria. The other four are far more often met with in hysterical than in non-hysterical subjects. Some observers consider the fourth and the seventh as special to hysteria but I prefer to regard all the last four skin conditions as an expression of a vaso-motor neurosis *plus* a toxæmia in varying proportions. All of these, I believe, are specially related to hysteria. Other skin diseases are without doubt influenced or modified by it, and Dr. Paul Briquet,[1] an analytical observer of great power, made the following important remark: "On sait quelle puissante influence les passions, et surtout le chagrin, les préoccupations et la contention de l'esprit, ont sur la production des maladies de la peau, et principalement sur celle des acnés, de la mentagre, et des ecthymas." This indirect influence very probably depends on the marked tendency in these subjects to vascular changes in the skin, but we shall only be concerned to day with those I have named.

1. *Attacks of pallor* of the surface generally accompany or alternate with some of the hysterical cerebral attacks which we have discussed on previous occasions.[2] Sometimes attacks of pallor occur alone, without cerebral manifestations of any kind, sometimes they alternate with flushings. Their explanation has already been fully dealt with. They are parts of what I have ventured to call "splanchnic storms" which are so common in hysteria and which, starting with an emotional disturbance, result in sudden dilatation of the splanchnic vascular area and consequent anæmia of the brain or the skin or, more frequently, of both.

2 *Attacks of flushing*, morbid blushing, and "flush storms" affecting part or the whole of the body are met with in all hysterical patients They are, in my experience, the most important of the stigmata of the hysterical diathesis and are one of the evidences of the vaso-motor instability, central and peripheral, which must be regarded as the essential somatic part of that diathesis. They are met with in all women at the menopause—at which time, by the way, the patient is often described as "hysterical"—but they occur throughout life from time to time in subjects of the hysterical diathesis. Dr Harry Campbell[3] has dealt so ably and so thoroughly with these morbid blushings and their pathology that I can add nothing to his admirable work. Speaking of their pathology he says: "For me, then, a so-called flush belongs to a very comprehensive class of nerve storm, closely allied to, and, in fact, sometimes indistinguishable from, an epileptic or an hysterical aura and starting like them in a nervous level situated high up, possibly even in the highest level, the parts ('nervous arrangements') involved being more particularly those which represent the organic viscera—above all, the thoracic viscera. The representatives of these parts in the highest centres constitute the chief physical basis of the emotions; and in women—in whom the emotional element is most fully developed—they are peculiarly unstable and liable to explode." Thus Dr. Campbell and I are practically in accord. An emotional state, he says, is the determining cause and this acts on the visceral nervous apparatus, sometimes on that in the thorax and sometimes on that in the abdomen. This is the same mechanism as that which I have just described to you. There is a sudden oscillatory dilatation or constriction of a visceral vascular area (splanchnic or thoracic), initiated in most cases by an emotional condition in the brain, and this is attended by a corresponding constriction or dilatation of the surface vessels. This same kind of storm can in some patients be determined by pressure on the peripheral terminations of the ilio-inguinal nerve (so-called "ovarian" region) which is in very close relation with the solar plexus.

3 Small, extremely fugitive *patches of congestion*, more or less abrupt in outline and localised to parts usually pale, such as the front or side of the neck, may be seen by any close observer in a great many patients who are subjects of the hysterical diathesis. Here, for instance is a note—one of many—made in my private case-book concerning a woman, aged 36 years, who consulted me for attacks of tremor of the hands, palpitation, associated with what she described as "bursting attacks," and other symptoms, all of entirely hysterical origin. While I was percussing her chest two or three patches of congestion varying in size from that of a threepenny-piece to that of half-a-crown appeared suddenly on both sides of the back and front of the chest, [illegible] not fading into the surrounding [illegible] ace, but terminating abruptly [illegible] like that of a map of Europe, [illegible] and passing away in a few minutes as suddenly as they came. She stated that she had been liable to these patches whenever she was nervous for as long as she could remember and her relatives had noticed them. I have often pointed out such fugitive patches in our hysterical patients occurring just below the ears, which seems to be their favourite situation, but they may occur anywhere. Their chief importance lies in the fact that they are definite and visible evidences of the abnormal reflex excitability of the vaso-motor centres. Just as in the flush storms we were considering the visceral vaso motor centres of the thorax or the abdomen are affected, so do these localised congestions depend on an abnormal irritability of the peripheral vaso-motor centres.

4. *Dermatographia* is a congestive streak which appears after a few seconds in the track of a scratch on the skin with some blunt article such as the top of a penholder. If an urticarial streak also appears it amounts to urticaria factitia. The latter we shall discuss shortly under exudative conditions. Dermatographia is regarded by some as of hysterical origin and a stigma of the hysterical diathesis, but others regard it as toxic. The latter is certainly not always true as in cases where the *sight* of an article of food which had previously produced urticaria determines an attack. The truth probably lies between these extremes. My own experience is that these streaks can be produced in [illegible] though much [illegible] ner. My belief [illegible] toxæmia, very often of gastro-intestinal origin, or some other cause of irritability of the nervous system. The "tache cérébrale" which Trousseau described as indicative of cerebral meningitis as distinct from enteric fever is dermatographia. Very generally some kind of toxæmia can be revealed, but a neuro-vascular irritability is the essential factor in the causation, either acquired as in tache cérébrale, or congenital and innate in the hysterical diathesis.

5. *Acroparæsthesia* (sensations of tingling, &c., in the extremities occurring for the most part in attacks) and *erythromelalgia* (redness and swelling of the extremities which, though paroxysmal, is more chronic in its duration)

have been already fully described.[4] They are most frequently met with in hysterical subjects and in the female sex, though they may be associated with other diseases. Out of a series of 45 cases (seven males and 38 females) which I have recently observed and of which a previous history was obtainable, 39 cases (five males and 34 females) presented either evidences or a history of hysterical manifestations. Similarly attacks of deadly white pallor of the fingers are more common in hysterical subjects.

6. *Exudative skin conditions* are almost, if not quite, as closely related to hysteria as are the last two skin conditions, strange as it may appear at first sight. Nevertheless, such disorders as urticaria, erythema, and localised circumscribed œdema are met with far more frequently in hysterical than in non-hysterical subjects, and though it is not sufficiently known may be determined purely by emotion, as in cases which I shall show you directly. Evidences of the hysterical diathesis can be revealed in between 85 and 90 per cent. of my hospital cases of urticaria factitia, erythema (all kinds), and circumscribed œdema taken collectively. There are three degrees of dermal exudation—serous effusion, consisting of lymph only, as in urticaria; sero sanguineous effusion, in which some of the blood corpuscles also escape from the blood-vessels, as evidenced by a certain degree of staining, as in chilblains or erythema nodosum; and purpuric effusion of all the blood elements. In regard to the etiology of these exudations I quite agree that they are very often in the main due to some alteration in the blood of an auto- or hetero-toxic kind. But I hold—and shall show you cases in proof—that they may also be dependent, at any rate in many instances, entirely or in large part on nervous (neuro-vascular and emotional) influences. And that is why these diseases are in general terms met with more commonly in the female, in hysterical and nervous subjects, in direct association with other neuro-vascular symptoms, and exhibit the same fugitive and other characters which other hysterical phenomena do. I do not wish to claim all exudative skin conditions as solely of nerve origin—far from it—but there are at least three ways in which they may be produced: (1) by chemical changes in the blood; (2) by nervous influences (neuro-vascular and emotional); and (3) by a combination of the two preceding causes. It is to this last class that I believe the majority of exudative skin conditions belong. When we come to deal with the etiology of hysteria I shall on a future occasion indicate what a large and important part gastro-intestinal conditions, especially such as result in autotoxis, play in the causation of all hysterical manifestations. This is important because if I am correct it brings the etiology of the two morbid conditions—exudative skin conditions and hysteria—more or less into line.

(*a*) Urticaria is the best known type of the *serous exudations*. It is in the great majority of instances traceable to an autotoxis of gastro-intestinal origin, but it may be also produced by emotion—with and even without any gastric disturbance. Dr. A. E. Wright at a discussion at the Medical Society of London[5] remarked that there was certainly a nervous influence in the exudative processes in the skin, and mentioned the case of a young surgeon who could produce an attack of urticaria at will by fixing his mind on the subject. A case of recurrent urticaria is referred to by Dr. Stelwagon,[6] where the condition was traceable to eye-strain. Dr. Stelwagon, writing of the etiology of urticaria, says: "The action of nervous influence, direct or indirect, is shown in a case [of urticaria] reported by Oliver, where the eruption was due to eye-strain, persisting or recurring when a change in lenses was necessary; his patient had been the subject of frequently recurring attacks for years, but after suitable fitting of glasses for diminishing vision full relief ensued; if not worn constantly the eruption would return, to disappear upon resuming their use; later the return was again persistent and was found due to vision changes requiring new lenses; on one occasion a mistake was made by the optician and the eruption again appeared." Professor M'Call Anderson[7] writes, under the causes of urticaria: "In some persons mental emotion is sufficient to call it forth, such as an excess of joy or grief. ...... Some remarkable cases of this kind have been reported by Alibert. He once saw a young woman who could not enter a drawing-room without having the whole skin covered with nettle rash, so much so that she could not dance or enjoy any other recreation; and an ecclesiastic who could not celebrate divin service because the eruption immediately came out an caused him to scratch himself with the greatest violence Dr. H. Radcliffe Crocker[8] states: "Everything in urtica points to its being primarily a vaso-motor disturbance, direct reflex, central or peripheral." He also refers to the emotion element in urticaria, particularly in the chronic or recurre variety; and he mentions the case of "a woman in who the advent of strangers produced urticaria and this sensitiv ness increased until a knock or ring at the front door woul determine an immediate outbreak."

Many other instances could be mentioned, but here is case, which I am fortunately able to show you, of urticari produced entirely by emotion. The little boy, aged eight an a half years, who was sent to me by Dr. M'Emin, had be taken away from school eight or nine weeks ago becau of the round raised wheals which appeared on the face an upper part of the trunk whenever he worried over his lesso or was teased by the other boys. In the evening an effo to learn his lessons will produce an attack and then th irritation prevents his making any further attempt. An emotion or source of nervousness will cause the eruption appear. His skin, which five minutes ago was quite clea is now, you observe, without having been touched in any wa covered with numerous small wheals owing to his nervousne in coming before us (Fig. 1). The spots consist of circula definitely raised urticarial patches of about the size of millet seeds or split peas surrounded as usual by a zone of congestion. The face and upper half of the trunk are alone affected

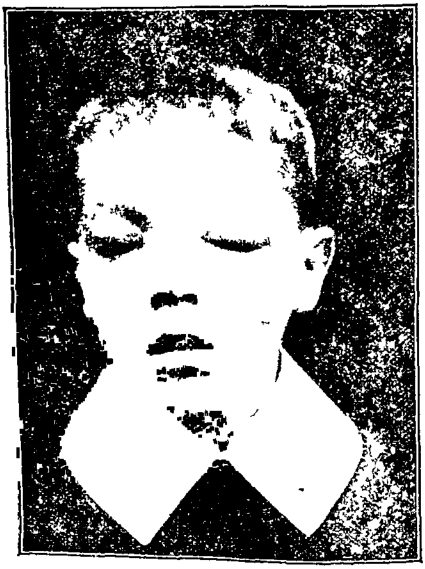
These attacks last about from one to three hours if the emotional cause is removed His mother says that he is an extremely nervous, excitable, and sensitive child His gastro intestinal functions are perfectly normal

Here is a case of urticaria factitia (urticaria produced by pressure) but nevertheless one which can also be determined by emotion The patient, now aged 16 years, was first brought to me four years ago at the age of 12 years, complaining that for the last month whenever she "washed her face in the morning it swelled and wheals came out", the same appearances came on the body She was noted as being a very nervous child, easily startled, and crying very easily A descending constant current to the spine was ordered and compound infusion of gentian and she recovered in a couple of months, remaining well till six or eight months ago She now comes complaining that "her face and other parts come up very red and swelled when she feels nervous or is worried about her work, or when the parts are touched"

The disease known as localised circumscribed œdema (giant urticaria, Quincke's disease, angioneurotic œdema) another serous exudation, though connected by some of the older authors with gastro intestinal disturbance is now admitted by others to be an angioneurosis That the attacks may be determined by emotional or angioneurotic conditions is evidenced by the following case which I am able to show you The patient is a single woman, aged 35 years and she has for the past nine months been troubled with localised œdematous swellings on the face every three or four weeks—namely, just before or just after the catamenial period, when she is also subject to nervous derangements which are not unusual at such times The swellings vary in size from that of a Barcelona nut to that of a walnut, are pinkish white in colour, and give rise to much irritation They are specially prone to affect the eye lids (as shown in Fig 2, which illustrates the next case) sometimes symmetrically, but they also occur on other parts of the face and occasionally in other parts of the body At times they vanish in an hour or two but may remain for a day She has neither indigestion, constipation nor any other abdominal abnormality and is at the present time in perfect health except for this troublesome condition She had "anæmia" as a girl and was subject to nervous attacks from time to time Calcium chloride has only given her partial relief and now I propose to try ichthyol and bromide of ammonium In this case there is not the slightest evidence pointing to any change in the blood or blood vessels The main cause must surely act through the neuro vascular apparatus, and the flushing which is so common in these subjects, especially at the catamenial period, takes the form in her of localised œdema The sudden onset and sudden disappearance of the lesions, without leaving a trace behind them, also support this view

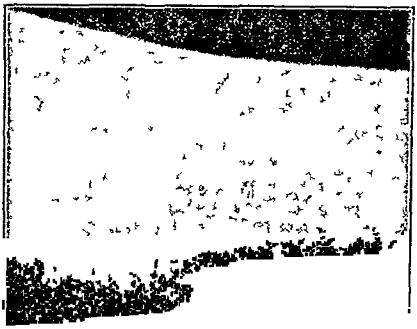
FIG 2.



Angioneurotic œdema in a boy aged six years

Here is another example of the same disease occurring in a child, six years old who was sent to me by Dr Evan Evans This picture (Fig 2) shows an œdematous swelling of his upper eyelids which came on quite suddenly and spontaneously and disappeared equally as suddenly next day He has had similar swellings across the face (when his features become unrecognisable), the scrotum the hand, and elsewhere, coming on in the same mysterious way This little boy has also had attacks of purpura from time to time so that there probably exists in him a defect in the blood as well as the neuro vascular defect Professor William Osler[9] has found that cases of angioneurotic œdema are sometimes benefited by the prolonged administration of small doses of trinitrin—another fact pointing to their neuro-vascular origin

FIG 3



Erythema gyratum in a woman 22 years of age

Hysterical œdema was described by Sydenham[10] in 1681 as one of the symptoms which might be associated with
hysterical attacks
the ankle, which
involving one ankl
greatest in the n
Benjamin Brodie[1] refers to the diffuse pale swelling of a limb which may follow prolonged hysterical pain in the part Professor J M Charcot[12] in addition to the œdème blanc des hystériques gives a very lucid description of a congestive form of hysterical œdema (œdème bleu) in which the swollen parts are cyanosed, cold, and exhibit scattered spots of red In one of his cases the condition could be reproduced by means of hypnotism It is probable that all the conditions described by these princes among clinical observers belonged to the same angioneurotic œdema which is met with largely if not exclusively among hysterical and nervous persons

(b) *Sero sanguineous exudation* is but a transitional form of the preceding as may be seen for example, in the two

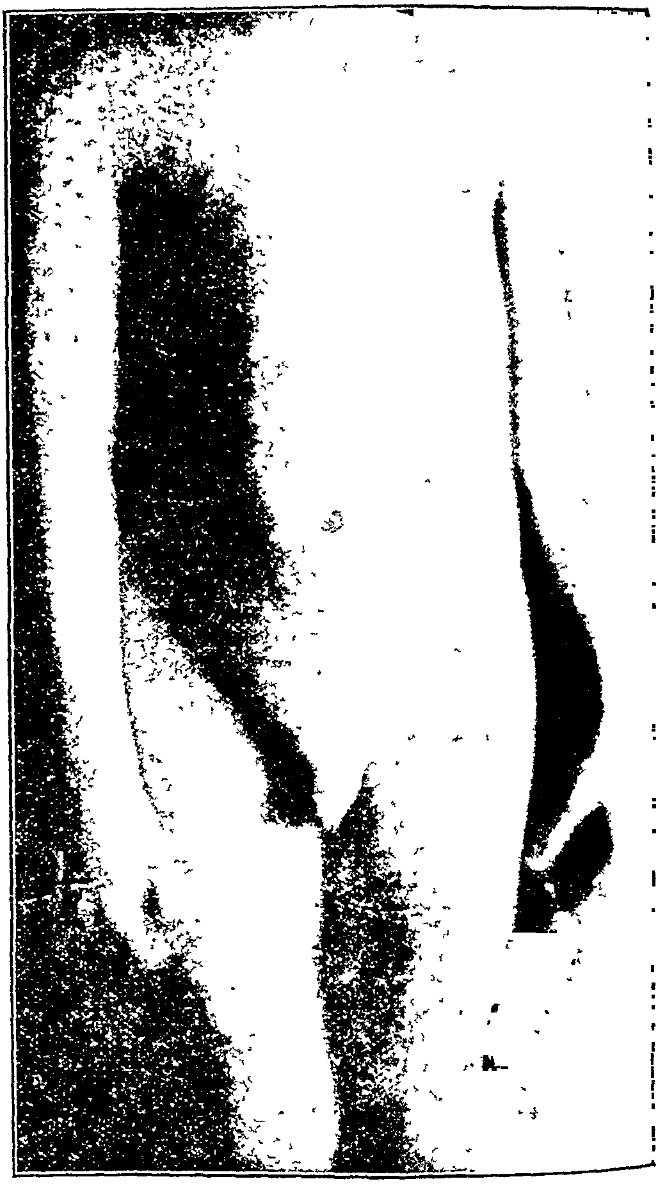
Profe

varieties of hysterical œdema described by Professor Charcot. Its best illustrations are to be met with among the erythemata. Erythema nodosum, for instance, one of the best known forms of erythema, is almost confined to young hysterical women with menstrual irregularities. I have frequently pointed out how often a history of this disease and erythema pernio (chilblains) is revealed in hysterical subjects and *vice versâ*, both the erythema and the hysteria being, in my view, indications of the morbid instability of the neuro-vascular centres. Erythema multiforme (including erythema annulare, erythema iris, erythema marginatum, erythema gyratum, and even erythema vesiculosum and bullosum, in which the exudation is sufficiently pronounced to produce vesicles and bullæ) is very generally regarded as either angio-neurotic or neuro-toxic in origin.[13] Its occurrence chiefly in young women, the strange way in which it comes and goes, and the associated phenomena, all point to the correctness of this view. In a good number of cases of erythema multiforme the exudation is only serous and it leaves no staining, as in this case of a young woman, aged 22 years (Fig. 3), who suffers from constantly recurring, somewhat fugitive, attacks of erythema gyratum on both forearms, especially when she is "upset" or nervous. You will note the symmetry and the associated hysterical phenomena. But in most cases the exudation is sero-sanguineous and the staining is more or less distinct. For instance, in this woman, aged 45 years, who is at the climacteric and who suffers from a widespread eruption of what is sometimes called purpuric erythema, the staining is very marked. I should also like to show you a boy suffering from a relatively rare disease, urticaria pigmentosa (of Sangster), in whom the associated hysterical features, both personal and hereditary, are sufficiently obvious. It is a condition closely allied to the foregoing, which appears in successive crops of urticaria, leaving behind them marked and persistent staining of a purpuric type. The patient is five years of age, and you will see that his body, limbs, and neck are covered with brownish-purple stains of different shades corresponding to their age. His mother tells us that "spots like nettle-rash" have been coming out in successive crops attended by a good deal of irritation ever since he was a few months old, and that they leave these stains, which very gradually fade away (Fig. 4). This little boy has once or twice passed blood in his stools and has had bleedings from the nose, so there probably exists in his case the dual cause of which I have spoken (hæmic and neuro-vascular). He is a very nervous and emotional child, his tears (his mother says) "are very near the surface" and he has attacks of extreme irritability of temper in which no one can do anything with him. At these times the spots are worse and even the face becomes affected. His mother has had "hysterical attacks" all her life, which have been especially marked during her pregnancies. There is said to be a "tendency to rashes" in the two other children but I have not seen them.

FIG. 4.



Case of urticaria pigmentosa in a boy five years of age.

(c) *Hæmorrhagic* or *purpuric effusions* have a less constant and less certain causal relationship with hysteria than any of the preceding, but it exists. I have notes of several cases where spontaneous hæmorrhage occurred from the ears, nose, or other mucous surfaces, as part of a hysterical seizure while the patient was under observation. Subcutaneous hæmorrhages have been described by several authors.[14] A recent case of "black chromidrosis with hysterical paralysis" described by Dr. Putnam of New York[15] probably comes under the category of hæmorrhagic effusion associated with secretory perversion. In this patient ink-black spots appeared on the skin whenever she was tired, and this condition and the associated hysterical paralysis which had lasted 14 months only cleared up when she went into the country. The taches and spontaneous hæmorrhages in the religious votaries of the Middle Ages were probably instances of hysterical hæmorrhage.

7. *Localised ischæmic conditions*—i.e., where there is a constriction of the arterioles of a given area, of one limb for example—are recognised by many observers among the manifestations of hysteria. For instance, Dr. J. A. Ormerod, in Professor Clifford Allbutt's System of Medicine, says: "Hysterical patients may present curious symptoms in the domain of the arterioles and capillaries. Limbs that are paralysed or anæsthetic may exhibit also 'ischæmia'; that is to say, when cut or pricked they bleed less freely than normally, or not at all. This is commonly ascribed to a vaso-motor spasm."[16] I think it is not sufficiently recognised that this ischæmic condition, using the term to mean spasm of the arterioles, may also occur quite independently of true paresis or true anæsthesia. The patient may complain of a "heaviness" or immobility of a part, yet there may be no actual loss of power. She may describe her abnormal sensations as a

---

[13] Vide Dr. Stelwagon: Diseases of the Skin, p 148 London and Philadelphia. Saunders and Co. Mr. Malcolm Morris (Diseases of the Skin, p. 102) Dr. Schwimmer (Die Neuropathischen Dermatonosen, p. 101), and Dr Lewin (Berliner Klinische Wochenschrift, No 23, 1876) consider it to be purely an angioneurosis. Dr. Radcliffe Crocker (loc. cit.) appears to regard it as inflammatory.

"numbness" or "prickling," yet she can feel when the part is touched and the more intelligent patients will tell you so spontaneously. The skin, when we are able to see it, may be normal in colour or it may be of waxy whiteness, especially when the end of a limb, as frequently happens, is mainly affected. The symptoms often start at the end of an extremity and spread upwards; sometimes all one side of the body is affected. The symptoms are always more or less transient and may be extremely fugitive. Sometimes they are associated with what I have described as hysterical cerebral attacks (Group A) or other hysterical manifestations, sometimes they occur alone, and sometimes, as in the following case, they are severe enough to constitute an attack in themselves. The clinical features of these symptoms—their transient nature, the pallor of the skin occasionally observed, the relative bloodlessness—stamp them undoubtedly as a vaso-motor spasm of the arterioles.

This patient, a single woman, 27 years of age, an extremely intelligent person, is suffering from what I believe to be ischæmic attacks of hemiplegic distribution. She gives us a lucid and typical history of the emotional and vaso-motor neurosis which we call hysteria. The hereditary taint is well marked. She herself was nervous and excitable as a child but studied her lessons well and was generally top of her classes. She volunteers the statement: "All my life I have been very liable to flush even when I was anæmic." Her history presents many dermal and circulatory symptoms. As a girl her hands used to become "red, mottled, and swelled in places, resembling chilblains, excepting that they were worse in summer than in winter." She was affected with what her medical attendant called "erythema nodosum" on the legs when she was 12 years of age and at 13 years began to menstruate. From that time until a year ago she has been subject to attacks of hysterical globus. Asked to describe them she says: "I first get very pale and the heart beats violently, than I get a sinking in the stomach which rises to the throat like a ball." She has also had attacks of violent palpitation without the globus and *vice versâ*, and other hysterical attacks, some of a syncopal type (Group A) All these attacks were more frequent at the menstrual period or when she was out of health, and were all determined by the slightest excitement. 12 months ago these attacks almost ceased but they were replaced by others of a worse kind, though they are started by exactly the same causes as the globus, flushings, tachycardia, and other hysterical attacks. It is for these that I am consulted In these a "numbness" or "dead feeling" (sometimes accompanied by "prickling of pins and needles") starts in the left thumb and "rushes down the left side like a wave into the leg," on one or two occasions spreading to the opposite side. She states that she can feel things when the affected parts are touched.. "The throat," she says, "feels swollen and the left half of my tongue feels numbed so that I cannot move it. A stupid kind of dazed feeling then comes over me, so that I cannot speak, though I know what is going on around me." The whole attack lasts from five to 15 minutes and it is generally followed by a splitting headache on the left half of the head, lasting some hours and only relieved by sleep. She has had an average of two or more of these attacks a week of varying severity. On one occasion I had the opportunity of witnessing one of these attacks. The left hand was pale and bloodless and when pricked with a needle did not bleed; she could feel with that hand, though not so well as with the other. One of these attacks, caused by running after and missing a train, was attended by distinct mental symptoms. She took the next train and while in it another severe attack came on. When met by her friends at her destination she was stated to be "delirious," doing and talking "silly things." This lasted an hour or two; then the mental confusion passed off as suddenly as it had come and she did not remember any of the silly things she had previously said or done. These seizures had given her much anxiety because her mother died at the age of 49 years from "paralysis after a stroke."

This patient presents the hysterogenic phenomenon to a certain extent [illegible] succeeded by pressure in [illegible] one of the "throat attack [illegible] a complete attack of the numbness. The organs are healthy, but all the superficial and deep reflexes are considerably exaggerated. I should like, just in passing, to refer to the treatment. On June 1st she commenced to take a mixture containing small doses of nux vomica and 15 grains of ammonium bromide thrice daily but she made very little improvement. On July 9th, her digestion being rather out of order, she took a mixture containing bicarbonate of sodium and gentian, with ammonium bromide as before, but there was only very slight improvement. On August 13th she commenced to take thrice daily 15 grains of calcium chloride and 15 grains of ammonium bromide, and the improvement was immediate and marked. Prior to August 13th she had been having attacks daily but for the past six weeks she has not had a single one. She was taking bromide all the time but the effect of the calcium chloride was almost magical. The fact of my having found this remedy useful in various forms of erythema induced me, in view of her history, to try it in her case. It is a most interesting one. Throughout life she has had unmistakeable hysterical attacks of various kinds—globus hystericus, tachycardia, and syncope. In early life she was troubled with various skin symptoms of a congestive and erythematous type, which we have seen are so frequent in hysterical subjects She has had several kinds of unmistakeably hysterical seizures. Latterly these have been replaced by attacks of hemiplegic "numbness" or dead feelings, starting in the left thumb, without loss of sensation and attended by pallor and bloodlessness—determined by the same causes as the other attacks. There can be no reasonable doubt that these latter attacks are also hysterical and are due to a widespread vaso-motor spasm starting from the centre controlling the vascular area of the left arm and spreading to the vaso-motor centre or centres of the left half of the body and head. At one stage of her history the vaso- [illegible] kind [illegible] ther [illegible] we [illegible] two (generalised pallor and flushings) are part of the "splanchnic storms" which form an integral part of hysteria. The third (the congestive patches) constitute visible evidences of the reflex excitability of the local vaso-motor mechanisms which also form part of the same disorder. The fourth, fifth, and sixth (dermatographia, acroparæsthesia, and exudative skin [illegible] products in widely varying proportions, of this [illegible] y *plus* hæmic changes. [illegible] ame pathology but is manifested as a vascular spasm only. Among the coöperating causes sometimes in operation may be mentioned toxins of gastro intestinal origin, articles of diet, traumatism, toxins of insects, and other causes to be considered hereafter. But without the vaso-motor instability, innate—i.e., hysterical—or acquired, these cannot act.

RESEMBLANCES OF THE SKIN TO THE CENTRAL NERVOUS SYSTEM.

I have entered at this length into hysterical skin symptoms and eruptions because, in the first place, I believe that the slighter and more transient pallor and congestions included in the first three classes above referred to are often overlooked and are hardly sufficiently recognised as part and parcel of the hysterical diathesis. They are, in my experience, veritable stigmata of hysteria. Secondly, I hope I have demonstrated that serous and sero-sanguineous effusions—urticaria, erythromelalgia, erythemata, ischæmic spasm, and even hæmorrhage—may be produced by the same emotional and other causes which determine undoubted hysterical manifestations and that these effusions depend in part or *in toto* on the neuro-vascular irritability and irregularity which form, in my view, the essential element of hysterical conditions. In committing myself to this statement I do not wish to exclude the toxic or blood factor in the causation of these effusions. In fact, a toxic or nutritional element can very often be revealed in these dermal effusions, *just as it can be in hysterical motor and sensory disorder* [illegible] *hysterical visceral attacks* (Group I [illegible] the [illegible] rent two factors are [illegible] cases Congestion, pallor, and ischæmic spasm may be, and generally are, of purely neuro-vascular (angioneurotic) and emotional origin, hæmorrhage may be purely toxic, while in serous and sero-sanguineous effusions the two factors are nearly always combined. In the third place, I hope to prove to you hereafter that these same lesions, pallor, flushing, congestion, exudation, ischæmia, and possibly even hæmorrhage, which we can see on the skin, may in like circumstances be determined in the central nervous system and other places and give rise to hysterical motor, sensory, visceral, and other symptoms, thus explaining one of the leading features of that strange disorder—namely, its "mimicry" of organic disease. It is as true to-day as it was in 1682, when Sydenham wrote, "Whatever part of the body it [hysteria] attacks it will create the proper symptom of that part. ...... Few of the maladies of miserable mortality are not imitated by it."

Fourthly, it is, however, in relation to the central nervous system that the best marked, the strangest, and the most definitely hysterical symptoms appear; and I should like, in conclusion, to indicate the marked resemblances—embryonic, physiological, and pathological—which exist between the integument and the central nervous system, structures which at first appear so different from one another. The first and most fundamental change which takes place in the development of the embryo is the arrangement of its cells into three distinct layers, the epiblast, hypoblast, and mesoblast. Now, from the epiblast both the tegumentary covering of the body and the central nervous system are developed. The central nervous system is formed solely by an infolding of the superficial cells of the embryo which afterwards form the skin; and these are the only two structures of the body which are developed from the epiblast. The physiological resemblance is to be found in the fact that whereas the skin with its tactile corpuscles, the eyes and other external sense organs (developed from the epiblast) represent the external projection of the sensorium, just as the central nervous system represents the internal projection of the sensorium. A consideration of syphilis affords a striking illustration of their pathological resemblance, for this disease is specially apt to affect both the skin and the central nervous system in preference to, though not to the exclusion of, the other parts of the body. Undoubtedly the places in which to study syphilis are in a skin and in a nerve clinic—and these, if I mistake not, are also the best places in which to study hysteria.

Oration

ON

THE SANATORIUM TREATMENT OF PULMONARY TUBERCULOSIS.

Delivered at the Opening Meeting of the Reading Pathological Society on Oct. 15th, 1903,

BY C. THEODORE WILLIAMS, M.A., M.D. OXON., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

GENTLEMEN,—I think we shall all agree that the introduction of sanatorium and hygienic treatment into the therapeutics of pulmonary tuberculosis has proved an undoubted boon to sufferers from that complaint, and while it has gone far to arrest the disease in initial cases it has also done much to mitigate the sufferings and to reduce the symptoms of the advanced cases and has given a very different aspect to the wards of consumption hospitals and Poor-law infirmaries. For the efficient treatment of consumption the first step is the separation of the consumptives from the healthy and their housing, not in the wards of a general hospital, as is still done in many continental hospitals the authorities of which ought to know better, but in separate buildings, the incipient cases in sanatoriums and the advanced cases in consumption hospitals with more complete arrangements for nursing and special treatment. It is the proud boast of this country that England was the first to recognise this important doctrine and to build consumption hospitals for the special treatment and study of such cases and this was done without reference to infection theories. At least four hospitals were established in London before it entered into the heads of our foreign neighbours to attempt anything of the sort.

Now it is generally recognised that consumptives should be separated, partly to prevent their infecting the healthy and partly because the open-air system, which for them is essential, is not suited to all kinds of disease. With the chief features of the open-air system you are all probably familiar and I do not propose to describe it in detail but to select certain points and on these to offer remarks based on personal experience and a careful examination of many sanatoriums and their arrangements. I may claim to have visited the principal sanatoriums of Germany, Switzerland, Sweden, and Denmark, as well as many in this country, and I am a member of the building committees of three sanatoriums, two of which are in course of construction, and I consequently have had some opportunity of gaining experience in the subject. I will first say a few words on sanatorium construction. It is not necessary to erect a building of great architectural pretensions or of a very solid character. Some sanatoriums which are apparently of great utility consist of a series of huts or one-storeyed cottages constructed of wood for sleeping rooms with a larger hut for dining room and kitchen. Such are the Docker huts in Germany and those of Dr. Denton Johns at Parkstone, near Bournemouth, and the Adirondack cottage sanatoriums in the United States, and some authorities prefer these to more permanent structures on account of their cheapness and of their necessitating an open-air life. But in bad weather there are difficulties, especially of service, and another trouble is the danger of fire. It has been found by experience that completeness of arrangement and organisation cannot be arrived at without solid and permanent buildings and the following may be regarded as essential elements of a well-organised institution as exemplified in all first-class European sanatoriums.

1. A block of two storeys or more facing south or south-east, containing the patients' bedrooms and the day rooms, with a corridor behind, out of which on the north side would open the sanitary towers containing bathrooms, water-closets, and slop-sinks; while in the basement would be the hydro-therapeutic department.

2. A block behind the first and connected with it, containing the dining rooms, kitchens, and on one side the medical officers' consulting rooms, sleeping rooms, and laboratories, and on the other the matron's and nurses' quarters.

3 An administration block placed at some distance from the first two to avoid noise, taking in the laundry, heating apparatus, electric plant, and the disinfector and other machinery and the mortuary.

4 An isolation block.

5. Medical superintendent's house. In most sanatoriums of any size there are three medical officers and the head physician usually has a house apart in the sanatorium precincts.

6. The Liegeballen or shelters. These can be connected with the patients' block or placed in front of the basement and form part of it, but they must not be placed in front of the patients' bedrooms which they would only darken.

Dr. Walther and his followers are opposed to Liegeballen altogether and think it inadvisable for a number of male or female patients to pass their rest hours together and prefer that they should repose in the solitude of their chambers. There are no doubt invalids who rest more completely when alone and in that case the resting hours should be passed on a private balcony with the air circulating round them as is so well contrived at the Wehrawald and Schatz Alp sanatoriums and not while lying on their beds, as is often done. However, for the mass of consumptives Liegeballen are, if not too crowded, excellent, as patients have their own reclining chair and table, on which is a *model* sputum bottle, and can have abundant wraps to keep them warm. A space of at least four feet wide should be allowed to each patient, so as to preclude all chance of infection through droplets as pointed out by Flügge. Here the inmates can pass a great part of the day in all weathers and can be easily supervised by the medical man. Warmth is maintained without difficulty in the prone position by the aid of blankets or woollen coverings and in the German people's sanatoriums the feet are incased in felt boots or plunged into a Fuss-sack as is the habit in Danish institutions. Liegeballen are generally from 10 to 15 feet in height and from 10 to 13 feet in depth, the length depending on the number of patients to be treated. If too lofty there is a difficulty in protecting from bad weather and sun and if too deep, the sun does not always penetrate to the innermost recesses. The rain or snow or sun glare is kept out by blinds drawn down from above or by curtains. These shelters facing the south often become too hot in summer and consequently a special set placed in the shade and facing north is provided in the grounds, or the shed is sometimes arranged to contain a double row of couches separated by a partition, those for winter facing south and those for summer facing north. All Liegehallen should have swing windows above the patients' heads to secure a cool current in warm weather. It is also advisable to have some rotatory shelters which can be arranged for protection from the prevalent winds, and these can be placed in different parts of the grounds. Such small shelters are very convenient for consumptives when treated in their own homes.

Every sanatorium must secure for the patients a bountiful supply of air, by night as well as by day, and in addition to the Liegehallen a certain number of rooms should be fitted with balconies protected with blinds from rain and glare on to which the beds of feverish patients can, when required, be wheeled through the window. All windows must be made to open, and the best plan is to have the upper portion falling in, louvre fashion, and the lower to open fully inwards as a French casement. The upper part will always be kept open by night and by day, and also, as a rule, the lower part, but when necessary to exclude storms or too strong light, jalousie blinds can be used. Over the door of each ward should be a swing window so as to admit of a through current of air even when the door is shut. Some sanatoriums have with great advantage double doors to exclude noise from the passages. All wards should be fully ten feet high, 11 feet is better, and some foreign sanatoriums allow 13 feet. There should be a space of not less than 1000 cubic feet per head. It is often urged that this cannot be essential with all the windows open, but it must be borne in mind that it is highly important to avoid wind and draught and the larger the air space the less likelihood there is of draughts. What is required for a consumptive is that the air should be continually renewed without his knowledge. If the open-air system is properly carried out there is no need for artificial ventilation, and though in many well-known sanatoriums some system exists it is unnecessary and being generally unused becomes a receptacle for dust.

A word about heating as I have touched on ventilation and here we have to confess that the coal fire and hearth, the stronghold of British domestic life, do not assimilate well with the open-air system but promote draughts. Fires often smoke under the ordeal of open windows and are not found to furnish sufficient or even heating, while they necessitate more labour. Central heating with radiators placed in the wards and corridors answers admirably and reduces service. It need not be added that electric lighting is the best for adoption.

GRADUATED EXERCISE.

This is a most important feature of the system and one that Brehmer dwelt on strongly, this being proved by the fine series of graded walks constructed at Görbersdorf which extend over miles of the park. Walther has planned his grounds with this view and all complete sanatoriums set aside a large portion of their property or utilise the neighbouring woods and paths for this purpose. The best plan is to give the patient the uphill at the commencement of his walk and the downhill at the end, and walks should be provided in sheltered places at gradients of 1 in 20, 1 in 10, and even 1 in 8. The most extensive and best arranged set of walks I have visited are at the Vejlefjord Sanatorium in Denmark, made under the supervision of Dr. Saugman, an old patient and afterwards medical assistant at Görbersdorf, the beautiful grounds of the sanatorium, extending over wooded hills and sloping to the sea, the purpose. Dr. Saugman has series, according to the strength licitously named them after the s on tuberculosis and on sanatoriums, so that we come across "Laennec's Vej," "Villemin's Vej," "Brehmer's Vej," "Dettweiler's Vej," and the like. The pace generally enjoined is about two miles an hour, and as Dr. P. Horton-Smith[1] well shows, this very slow walking requires sustained muscular exertion and is not the easy toddle that might be supposed. In the German and foreign sanatoriums generally walking is the only exercise recommended, chiefly because other forms are not understood, but for English men and women who love games there is no reason why some moderate game, such as golf or croquet, should not be introduced for some patients, which certainly renders o of the English or three days a w raduated exercise. Muscular strength is gained, appetite increases, the processes of digestion and assimilation are stimulated, sleep is promoted, the standard of nutrition is raised, the respiratory power is augmented, the depth of inspiration is increased, and some enlargement of the thorax takes place, and though this does not equal what is achieved at high *altitudes something is done in this direction.*

An abundant dietary, representing all groups of food, is requisite to sustain the patient against the bacillar attack, but we hear too much of gain of weight and too little of gain of muscular power. When a patient is stated to have gained a stone or two or three stones during six months' residence in a sanatorium this is generally in the form of fat and such increase speedily vanishes when the stuffing process ceases. In patients with extensive excavation and probable aneurysmal dilatations of branches of the pulmonary artery from exposure in the cavity, the gorging of the vascular system from a very rich and plentiful dietary often leads to rupture of the vessels and fatal hæmoptysis, so *that it is desirable* not to stuff the individual with as much as he can assimilate but with as much as his vascular system can safely bear. Gain of weight is easily accomplished and is often as much due to want of exercise, as is seen during sea voyages, as to large feeding. It can be attained even in pyrexial cases if the patient be confined to bed while the stuffing goes on, as I showed many years ago at the Brompton Hospital.[2] It is too much the fashion to cite improvement and even ortunately we find disease is extending, and many a sanatorium medical officer has lamented to me over the fact that improvement in general condition is not always accompanied by improvement in the physical signs. Unless by means of regulated exercise we improve muscular vigour a large gain of weight is not much advantage.

MEASURES OF DISINFECTION.

The sputum must either be disinfected by high-pressure steam or strong carbolic acid—5 per cent.—or, what is very convenient, mixed with sawdust and burnt in a furnace or automatic destructor. At many sanatoriums peat is used for the purpose and in olden days at the Brompton Hospital immediately after the discovery of the tubercle bacillus the sputum was stirred in with the small coal used in the furnaces and thus consumed. At present it is burnt in an automatic destructor and the sputum cups are sterilised by steam. Dettweiler's pocket flask seems the best for the use of patients who are out on walks and in the Liegehallen, but where it is necessary to supply spittoons in passages and halls it is advisable to place them not on the floor but at a height of four or five feet above it so as to facilitate a safe lodgment of the sputum.

Patients' clothes should be disinfected with steam before being washed. All mattresses, blankets, pillows, and cushions should pass through the disinfecting chamber and the patients' rooms after they leave should be disinfected by formalin vapour. In the construction of the sanatorium and its fittings and furniture care must be taken to avoid any ledges or crannies on which dust can collect. The experiments of Flügge and others have proved that not only is dried sputum a possible source of infection but that the droplets ejected by a consumptive in the act of coughing or conversing may also prove a danger, and Fraenkel and others ed by the spray it not wonderful chest hospitals and their assistants in close conversation for hours together not more often affected? s on the few experiments to ignore the great and obvious living experiments which we witness any day in our consumptive hospitals and sanatoriums. When we are informed that the cough spray drop containing tubercle bacilli contains them in a high degree of virulence and we know that a large number of medical men, nurses, and students inhale these droplets every day and escape infection altogether, we must conclude that there is something in the human organism which specially protects it from the bacillar attack and renders it more or less invulnerable.

---

HYDRO-THERAPEUTICS.

For the greater number of consumptive patients, and especially in the cases of limited tuberculous consolidation, some form of bath is desirable. The "daily tub" of cold or tepid water when patients are without fever has a bracing effect on the nervous and muscular systems and promotes appetite, while the douche or shower bath, if the patients be strong enough, causes them to take deep inspirations and consequently produces more complete aeration of the lungs. All well-organised sanatoriums are provided with a good hydro-therapeutic department.

SUN BATH.

This treatment, which I believe originated in South Austria, is practised in certain sanatoriums and is well worth a study. The patients, with the smallest modicum of clothing, lie at full length in the open on mats exposed to the sun's rays in the hottest part of the day for periods varying from a quarter of an hour to one and a half hours and are then rubbed down or have a douche or shower bath administered before the friction. Dr. Saugman of Vejlefjord reports that the sun bath is popular with consumptives who are in no great hurry to resume their clothes. After the sun bath the rectal temperature rises two, six, and even eight points Centigrade, reaching 38·1° (100 3° F.) or 38·3° C. (100·9° F.) and then falling very quickly. After many baths the daily rise is only one point Centigrade and in some patients even a fall of temperature was noted. Appetite was generally increased, but no great influence was observed on weight. Patients with stationary weights appeared to fall off, while those with rising weights continued to gain. Dr. Saugman gives an account of 26 consumptives who were given these baths—13 men and 13 women—five in the first stage (Turban), six in the second stage, and 15 in the third stage. 20 patients improved from the treatment, but two ladies gave up after the first bath, one on account of the languor induced thereby. Two patients suffered from erythema and in one it was accompanied by considerable fever. This lady, however, eventually became accustomed to the baths and was able to endure them from 20 to 40 minutes without discomfort. In one case the bath was followed by a rise of temperature and dry pleurisy. Cases of strumous joints seem to do well under this treatment.

Dr. Denton Johns showed me some patients whom he had submitted to sun-bath treatment even in the months of February and March. They were well developed and splendidly tanned and looked pretty vigorous generally. The great difficulty in this country is to provide a sequestered spot for the sun bath and Dr. Johns has utilised for male patients an old high-walled circular fruit garden for the purpose, which is arranged with mats on a sunny slope with a good douche at hand. He has placed the ladies in a pit-like depression of the grounds, well sheltered from the vulgar gaze, and during the hour of the bath a flag is hoisted to warn off all intruders.

SANATORIAL RESULTS.

Let us now inquire what results have been obtained from the sanatorium treatment of consumption which has been in vogue for some years in Germany and Switzerland and of which tolerably trustworthy statistics have lately been published. The German Imperial Board of Health[3] has been collecting statistics of the sanatoriums since the year 1896 based on 6000 cases kept under observation until 1901 with the following result. Of every 100 sanatorium patients at the close of the treatment (presumably three to six months) 67·3 per cent. were capable of resuming work in their former calling; 7·1 per cent. undertook occupation of a less arduous nature; 14 6 per cent. were partly capable of work; and 11 per cent. were incapable of work. This, of course, is regarding results from the invalidity insurance point of view, but stated generally the results are: 87·7 per cent. were dismissed as cured or improved; 8·8 per cent. were not improved; 3·1 per cent. were worse; and 0·5 per cent. died. Of the patients who came in the first stage the percentage of "improved" reached 96·2 and of those in the second stage, 89·9. We must bear in mind that these figures are supplied by the sanatoriums themselves to the Imperial insurance department which is not answerable for their accuracy and therefore the first classification according to the ability to work is valuable as a means of checking these last figures. The insurance statistics further show that for the years 1897, 1898, 1899, 1900, and 1901 "at the conclusion of the sanatorium treatment, there was a successful result excluding in all probability the appearance of invalidity in the near future" among those insured. The subjoined table (Table I.) shows the percentages of those discharged fit for work and their gradual reduction after leaving the sanatoriums.

TABLE I.—*Showing the After-results of German Sanatoriums in 6000 Consumptives.*

—	Discharged from sanatoriums capable of work.				
	1897.	1898.	1899.	1900.	1901.
	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
—	68	74	74	72	77
At close of 1898	44	—	—	—	—
At close of 1899	30	—	—	—	—
At close of 1900	30	—	—	—	—
At close of 1901	27	—	—	—	—

The question naturally arises how far these results were permanent and this is answered by the statement that the success of the treatment obtained in 1897 (68 per cent.) had lasted till the close of 1898, 1899, 1900, and 1901 in 44, 30, 30, and 27 per cent. respectively of the persons under permanent supervision. This does not say much for the durability of the arrest of the disease as in four years 41 per cent. had relapsed. But according to the German authorities the State and the family ought to be grateful if the ability to work is preserved to a man even for some years who otherwise would have fallen a victim earlier to disease or death and thus the expense of maintaining sanatoriums is justified. They remark, as worthy of note, that a few of the patients who were admitted into the sanatoriums with advanced tuberculosis and were afterwards discharged as "not improved" were found to be on subsequent examination completely capable of work.

Dr. Schmid,[4] the director of the Swiss Health Office, has published a noteworthy report on the results of six public sanatoriums with an aggregate of 366 beds for the years 1899 to 1901. The report has been made under considerable difficulties, as each institution framed its results in a different way, but the particulars and conclusions are most valuable and well worth study. The total number of patients used for these statistics is 2954, among whom the male sex slightly preponderated and included a large proportion of severe cases. 547 patients were admitted with pyrexia of various degrees and some of these never lost it; 1189 were admitted without fever. Of these patients 38·5 per cent. were in the first stage of Turban's[5] category, 34 5 per cent. were in his second stage, and 27 per cent. were severe cases in his third, so there were a considerable number of advanced cases. The sanatoriums included Heiligen-Schwendi, altitude 3224 feet; Wald, 2925 feet; Braunwald, 4920 feet; Leysin, 4800 feet; Malvilliers, 3900 feet; and Basel-Davos, 5200 feet; all therefore were at fair altitudes. These patients appear to have belonged chiefly to the middle and lower classes. The length of stay in the sanatoriums varied from 70 to 204 days but averaged four months each.

The results of the treatment may be stated as follows: Of the total number at the time of leaving the sanatoriums 82 5 per cent. had improved; 16·2 per cent. had not improved; and 0 8 per cent had died. Classifying by the capacity for work, in from 48 to 50·9 per cent., or about half, arrest of the disease took place, and about one-third were fit for work for a longer or shorter time. Only one-sixth did not recover their power of labour. The effect of extent of disease and stage is well shown in Table II.

---

[3] Tuberculosis, June, 1903.

[4] Tuberculosis, July, 1903.

[5] Turban includes under the first stage slight cases, where the disease affects, at the least, one lobe or two half lobes. In the second stage are more extensively affected patients with either two lobes involved, or one severely so, and softening or excavation present. The third stage includes all other degrees of disease not embraced in the first and second stages.

TABLE II.—*Showing the Influence of Stage.*

On discharge.	Stage. First.	Stage. Second.	Stage. Third.
	Per cent.	Per cent.	Per cent.
Work power unimpaired	83·9	40·6	10·1
" " but little impaired	14·1	47·6	34·5
" " much impaired ...	2·0	11·8	55·4

The most interesting part of the whole paper is the account *of the after-results in these patients which has been drawn* up by an entirely impartial committee consisting of three Basle professors—Dr. Egger, Dr. Hägler, and Dr. von der Mühls—but unfortunately it only deals with the results of one institution—viz., the Basel-Davos Sanatorium. We here learn what has become of the patients during the years since they left Davos, and this record is very satisfactory, a marked contrast to the German sanatorium results (*vide* Table III.).

TABLE III.—*Showing the After results of Basel Davos Sanatorium.*

—	Discharged. 1897. Well and capable of work.	1897. Partly or not capable.	1897. Died.	1893. Well and capable of work.	1893. Partly or not capable.	1893. Died.	1899. Well and capable of work.	1899. Partly or not capable.	1899. Died.	1900. Well and capable of work.	1900. Partly or not capable.	1900. Died.
	%	%	%	%	%	%	%	%	%	%	%	%
At close of 1899	70·1	5·1	24·8	67·4	13·8	18·8	—	—	—	—	—	—
At close of 1900	64·3	5·1	30·6	62·6	8·1	29·3	63·1	17·4	19·5	—	—	—

Table IV. shows the influence of degree and stage at the patient's admission to the sanatorium on the after-results and points out clearly the importance (1) of early admission to treatment and (2) the unsuitability of the advanced cases for sanatoriums; hence the absolute necessity of consumption hospitals where these cases may receive appropriate medicinal treatment and nursing.

TABLE IV.—*Showing the Influence of Degree of Disease when admitted on After results.*

	%	%	%	%	%	%	%	%	%	%	%	%
(Turban) Stage 1	84·3	2·0	13·7	81·6	5·3	13·1	81·9	10·9	7·2	97·1	2·9	0·0
Stage 2	46·4	7·2	46·4	32·2	21·4	46·4	47·8	17·4	34·8	58·2	11·6	30·2
Stage 3	5·3	10·5	84·2	17·4	8·7	73·9	8·0	8·0	84·0	21·1	26·3	52·6

The superiority of the Swiss over the German results confirms an opinion that I have long held and published that the climate of high altitudes exercises a most valuable healing influence—equalled by no other conditions—over tuberculosis of the lung and disproves the absurd opinions lately promulgated that climate has no influence in the treatment of consumption. The results of the English sanatoriums have not as yet been sufficiently large and complete to permit of comparison with the German and Swiss statistics. Dr. F. W. Burton-Fanning's report on the results of sanatorium treatment in the United Kingdom published in the Transactions of the British Congress on Tuberculosis (1901) was too scanty to enable clear deductions to be drawn, but his recent paper on three years' results of Mundesley Sanatorium[6] contains some interesting conclusions though the number of cases (146) is too small to justify definite deductions. 84·60 per cent. of his patients improved and only 15·38 received no benefit. Since they quitted the sanatorium 43 have died (two not from tuberculosis); the greater part of the remainder seem to be in good condition and even able to work. I have other sanatorium statistics from England and the United States but on a smaller scale than the Swiss and German and therefore less trustworthy for conclusions; but although we may hope for better results as the sanatoriums develop and improve, and especially when the unsuitable cases can be housed separately, we find so far that although sanatoriums are a great boon to consumptives they cannot be depended on to arrest tuberculous disease beyond all chance of relapse. They may, however, be expected to produce great improvement in all except advanced cases. In all but these we may look for reduction of temperature and pulse-rate, lessening of cough and improvement of respiration, disappearance of night sweats, gain of weight, and increase of muscular power. Many patients leave sanatoriums with no cough, no bacilli in the sputum, with diminished physical signs, and with the appearance of healthy men and women.

The educational value of sanatoriums must never be overlooked; the patient, having been trained to deal with his sputum and other secretions, is no longer a source of danger to his neighbours and he returns to his family and friends as the apostle of fresh air and wholesome living and the opponent of all those sins against hygiene and common sense which produce physiological misery and degrade the human constitution, while they surely tend to decay and death. Such an apostle, though sometimes trying in a household where the parents are aged or suffer from bronchitis and rheumatism, does incalculable good, and especially in the dwellings of the poor, and enforces his gospel by example as well as by precept.

I have spoken of sanatoriums, but it should be remembered that the open-air system is now practised in all the consumption hospitals of London and that the report of the Brompton Hospital, which is by far the largest institution, shows a considerable rise in the number of the improved class, even in advanced cases, since its introduction. We must not be satisfied with the sanatorium treatment of consumption alone but endeavour to discover other weapons to employ in our warfare against the terrible foe. Antituberculous serum has had only a limited trial and in some cases in which I employed it it certainly offered a prospect of future success if persevered in. Medicine accomplished much before the open-air system was introduced and should be combined with it and climate has proved over and over again of the greatest efficacy.

---

[6] THE LANCET, August 15th, 1903, p. 453.

SOCIETY FOR THE STATE REGISTRATION OF TRAINED NURSES.—At a special general meeting of this society, held in London on Jan. 23rd, at which Miss Isla Stewart, matron of St. Bartholomew's Hospital, presided, amendments to the Draft Bill of the society were considered. The Bill will be introduced into the House of Commons during the coming session by Dr. R. Farquharson, M.P. for West Aberdeenshire. The following Members of Parliament have also promised to back the Bill:—Sir Thomas Wrightson, Bart., Member for East St. Pancras; Sir John Batty Tuke, M.D. Edin., Member for Edinburgh and St. Andrews Universities; Mr. Hugh Crawford Smith, Member for Tyneside division of Northumberland; Mr. R. C. Munro-Ferguson, Member for Leith Burghs; Mr. H. J. Tennant, Member for Berwickshire; Mr. Alexander W. Black, Member for Banffshire; The Right Hon R B. Haldane, Member for Haddingtonshire; Sir Jam [illegible] C[illegible]ster-le Street, Durham; [illegible] Member for Thornbury; Mr. [illegible] Harry Trelawney Eve, divis[illegible] Member for Mid-Devon; and Dr. Edward Charles Thompson, F.R.C.S. An Introductory Address

ON

THE RELATION OF THE MEDICAL PRACTITIONER TO PREVENTIVE MEASURES AGAINST TUBERCULOSIS.

Delivered at the Post-graduate Course of the Mount Vernon Hospital for Consumption and Diseases of the Chest on Jan. 7th, 1904,

By ARTHUR NEWSHOLME, M.D.,
F.R.C.P. LOND,
MEDICAL OFFICER OF HEALTH OF BRIGHTON.

GENTLEMEN,—When asked to give an address in connexion with this post-graduate course a consideration of the preventive measures, and particularly the public preventive measures, against tuberculosis from the family practitioner's standpoint appeared likely to yield matter of interest and importance. For five years I have been practically engaged as medical officer of health in work on this subject from the standpoint of public health in connexion with a system of voluntary notification of cases of pulmonary tuberculosis which has been in operation in Brighton since January, 1899. To-day I ask you to consider some aspects of the same subject in the light of the relationship between the medical practitioner and the patient on the one hand and between these two and the medical officer of health on the other. Our main conclusion will be, I believe, that the professional duty of the practitioner and the private welfare of the patient are not only completely compatible with, but are, in fact, best advanced by, a complete adoption of the measures which the interests of public health demand.

It may be taken as accepted that pulmonary tuberculosis (or phthisis, as it will be named throughout) is an infectious disease which is capable of being communicated from sick to healthy. The conception of necessary preventive measures will vary according to the view taken as to the degree of infectivity and it is necessary therefore to give a preliminary consideration to this point. True, infection is followed by active disease in only a relatively small proportion of those acquiring it. But as in some 50 to 60 per cent. of the necropsies made in hospitals signs of old tuberculous lesions, cured by calcification or fibrosis, have been found, it follows that in a very large proportion of the total population a struggle has occurred between host and unwelcome guest, the former having in these instances come off victor. And although so many in the end escape an obvious attack of clinical tuberculosis, the number who are susceptible and fall victims to the infection is very large in proportion to the total population. Thus all forms of tuberculosis caused a death-rate in England of 1·8 per 1000 in 1902. If we assume that there are three persons constantly ill with tuberculosis for every death, then one in 185 of the total population suffers from tuberculosis, or on the assumption of uniform distribution approximately 1 in every 35 families. If we instance the life period from 35 to 45 years and confine ourselves to phthisis we find that in 1896–1900 the death-rate from phthisis was about 1 in 330 of the male and 1 in 500 of the female population at these ages. In calculating the duration of sickness involved in the deaths at these ages I prefer to take five years instead of three as the average duration of sickness in fatal cases as being in my experience nearer the truth. It is well known that the attack of phthisis ending in death has often been preceded by earlier attacks from which the patient has temporarily recovered. On this five years basis 1 in 66 of the men and 1 in 100 of the women aged from 35 to 45 years are at any one time ill with attacks of phthisis which eventually prove fatal. This estimate does not include the enormously larger number of cases which end in recovery or quiescence. Between the 1 in 66 or 1 in 100 of the adult population who suffer from phthisis ending in death and the 50 per cent. of total necropsies from all causes of death in which healed tuberculosis is found there are numerous minor degrees of sickness which have been overlooked but which have had their effect in diminishing the efficiency and enjoyment of life, and it may be added in disseminating infection. Our own experience must tell us that it would be difficult to make accurate inquiries into the history of three or four families without coming upon evidence of tuberculous disease. Such a large proportion of the total population suffers from active tuberculosis, happily in most instances not fatal, as to render it unwise and unsafe to act on the supposition that very exceptional susceptibility is required before active tuberculosis is developed.

At the same time, there need be no hesitation in agreeing that what Dr. T. Clifford Allbutt[1] happily describes as an "openness to consumption" is an important influence in favouring the growth of the seeds of this disease. The same remark would apply, probably almost equally, to many of the acute infectious diseases. For some years past I have kept a record of all the susceptible persons—i.e., those not having previously suffered from an attack of the same disease, in houses in which cases of diphtheria and scarlet fever have occurred. Owing to failures to secure early medical treatment and in recognition of these cases their notification is frequently delayed and the majority of presumably susceptible persons have been exposed to infection for two or three days before isolation was begun. And yet only 22 per cent. of the persons not previously having had scarlet fever who were temporarily exposed to infection developed the disease. The escape from attack of the majority of those drinking water or milk containing the germs of enteric fever can similarly not be sufficiently explained on the supposition which would explain the escape of a soldier in battle from being shot when bullets were flying about. Some persons are less susceptible than others to each of the infectious diseases and such persons only become infected when the virulence of the contagium is exceptionally great or the dose of contagium is exceptionally large or frequently repeated, or personal susceptibility is temporarily increased by dissipation or over fatigue or mental distress or by an intercurrent illness like influenza. Obviously there must be exposure to infection before it can operate and it will furthermore be agreed that dosage and particularly cumulative dosage of infection is a pre-eminently important factor in producing tuberculosis. If it be admitted that day for day tuberculosis is less easily communicable than most acute infective diseases the difference in the duration of infectivity is to be set against this. The healthy occupants of a phthisical home, especially among the poor, may be compared to a city which is subjected to a protracted siege, in which the combined effect of arms, deficient nutrition, and depressing emotions are at work. The inhabitants of such a city may escape with but little damage if the siege is raised at a comparatively early period; but they succumb in large numbers if it is prolonged. Similarly, the healthy members of a phthisically invaded household may be able to withstand infection if the disease is diagnosed early and if precautionary measures are at once begun and are continued thereafter; but they eventually fall victims to the repeated doses of infection if ignorance or fatalistic inertia prevails.

It is, however, urged by many that indirect measures not specially directed against tuberculosis have been in the past the main causes of the great decline in the death-rate from this disease which has occurred, and they will suffice for the future. Stress is properly laid on proper dwellings with efficient through ventilation and access of sunlight, and even more on a high condition of personal nutrition. These are important factors both in the prevention and the cure of phthisis. It is necessary, nevertheless, to preserve a sense of perspective in our preventive measures. Doubtless phthisis is most common among the poor whose conditions are a contrast to those just enumerated. But phthisis is caused by phthisis and does not occur, so far as we know, apart from the existence of a previous patient suffering from this disease. The tubercle bacillus is not ubiquitous. It haunts the vicinity of the consumptive. An extensive experience among notified cases compels me to the conclusion that defective nutrition, insufficient sunlight and ventilation, and domestic uncleanliness are mere adjuvants to the spread of infection and that this spread may occur in their absence. Unless cleanliness involves also the prompt destruction of infective material infection may spread almost regardless of environment. In the following instance such spread occurred to servant maids belonging to a family which had never previously suffered from tuberculosis, although the sanitary conditions of their mistress's house were, apart from the lack of precautions in connexion with the mistress's illness, perfect

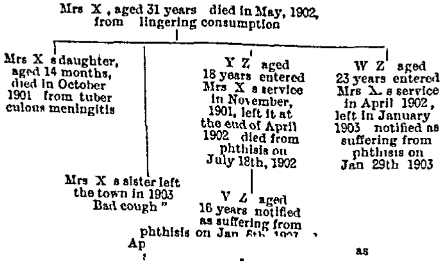
---

[1] Brit. Med. Jour., Oct. 28th, 1899, p. 1149.

Mrs X lived in a large house open to the sea, and in an excellent sanitary condition After several years' illness she died from phthisis in May, 1902 The disease was acquired before coming to the town As shown in the following scheme her only child died seven months earlier from tuberculous meningitis and her sister who nursed her for some months before she died had a "very bad cough" when she left the town some months after Mrs X 's death

Y Z, aged 18 years, entered Mrs X 's service as general servant in November, 1901 One of her daily duties was to wash Mrs X 's handkerchiefs and to clean out her spittoon No precautionary instructions were ever given to her She left her place in the following April when she was admitted to hospital suffering from "bronchitis and pleurisy" Before entering Mrs X 's service she had been in good health She subsequently returned to her mother's home and died there from acute phthisis on July 18th, 1902 Her brother, V. Z, living at the same address, who, up to the onset of his illness had a healthy outdoor occupation (driving a cart for a news agent) was notified on Jan 6th, 1903 to be suffering from phthisis He was then stated to have been ill for only nine weeks, though he looked ill for a few weeks previously The early diagnosis was made in consequence of the detection of tubercle bacilli in his sputum He died from acute phthisis on April 30th, 1903 Meanwhile a sister, W Z, entered Mrs X 's service just before her sister Y Z left it, and took on the latter's duties, except that she declined to wash the handkerchiefs of the patient (These were sent to wash without any preliminary treatment What about the poor "sorter" at the laundry?) Mrs X 's sister now washed out the spittoons W. Z swept out the sick room. She remained in Mrs X 's service until January, 1903 and as she frequently visited her sister Y Z during this time she had double opportunities of infection, assuming carelessness on the part of either patient. On Jan 29th, 1903, W Z was notified to be suffering from phthisis She was admitted to the borough sanatorium on Feb 19th and discharged on March 21st greatly improved On June 4th she was readmitted owing to a return of cough and expectoration She left on July 2nd and since then has kept well and is in domestic service (She was seen in January, 1904, and had continued to make weight)

The Z family consisted of the two phthisical sisters and the phthisical brother mentioned above, their father and mother, and another sister, aged 20 years There is no history of phthisis in the family It cannot, I think, be doubted that this family owed the decimating invasion of tuberculosis to the lax medical and nursing arrangements of Mrs X 's household



Mrs X, aged 31 years died in May, 1902, from lingering consumption
Mrs X 's daughter, aged 14 months, died in October 1901 from tuberculous meningitis
Mrs X 's sister left the town in 1903 Bad cough "
Y Z aged 18 years entered Mrs X 's service in November, 1901, left it at the end of April 1902 died from phthisis on July 18th, 1902
W Z aged 23 years entered Mrs X 's service in April 1902, left in January 1903 notified as suffering from phthisis on Jan 29th 1903
V Z aged 16 years notified as suffering from phthisis on Jan 6th 1903
Ap
as

Such cases as the above—and the experience of most medical men will furnish somewhat similar instances—indicate that statements like the following must be received *cum grano salis* "The testimony of experience . should, I think, be sufficient to satisfy us that the communicability of pulmonary tuberculosis can only be contrasted, not compared, with diseases such as small pox, typhus fever, or whooping cough It cannot, indeed, be compared with the communicability of enteric fever which is, perhaps, the least communicable of the diseases which are at present classed together as the infectious diseases and concerning which preventive measures are taken "[2] The limited communicability of enteric fever is, I venture to maintain, strictly comparable with that of tuberculosis Accurate statistics on a sufficiently large scale of the incidence of enteric fever and phthisis respectively among nurses or relatives engaged in nursing each of these diseases would go far towards settling this point In order to solve the problem they would need to be more definite and complete than those supplied to Dr. Bulstrode on the basis of the experience of the Ventnor Hospital On these no reliable conclusion can be based.[3] Phthisis is rarely acquired by nurses in public institutions; so with enteric fever Phthisis is frequently acquired by nurses or relatives in private houses, so with enteric fever. That is all that can be said until more exact facts are available

The relative rarity of infection of hospital nurses by tuberculosis is important from the medical practitioner's stand-

following scheme sets forth the main precautionary measures that are required —

- I The infection
  - 1 Dose
  - 2 Cumulative dosage
  - 3 Closeness of contact
  - 4 Lack or absence of precautions
  - 5 Defective ventilation and cleansing of rooms
- II Receptivity
  - 1 Inherited
  - 2 Acquired
    - 1 Exhaustion from nursing &c
    - 2 Depressing emotions
    - 3 Insufficient nutrition
    - 4 Defective ventilation and cleansing of rooms

This scheme does not pretend to be logical or exhaustive but it serves to draw attention to some of the more important points

In hospitals, long before the communicability of phthisis was recognised, expectoration was received into spittoons and large dosage of infection was thus prevented Similarly hospital wards have usually been well ventilated and kept scrupulously clean, all surfaces both of walls and floors being washable Again, hospital nurses are not so long on duty as wives or other relatives, the contact between them and the patient is less intimate as well as less prolonged than that of home nurses they have periodical holidays, are well fed, and are not subjected to the same extent to the influence of depressing emotions or of insanitary house conditions They are better trained in regard to the washing of hands and other personal precautions In view of the above circumstances the difference between the infectivity of phthisis and of enteric fever in hospital and in private practice is easily understood Which of these two diseases is the more communicable remains to be proved.

I can imagine no better means of converting those who underrate the infectivity of tuberculosis than the task of administering the notification of this disease in a large town, of interviewing some 200 patients each year, of examining over 100 patients who are yearly treated for a month each in our borough sanatorium with a view to train them so as to diminish the probability of their continuing sources of infection, of obtaining the family and personal histories of each of these and tracing as one gradually comes to do,
links of infec
be conclusive,
as any evider
disease of chronic course

We can all agree that the tubercle bacillus varies greatly in infectivity and virulence We know it does so when grown in the laboratory In varying in a similar fashion clinically it but follows the fashion of all the recognised infectious diseases Obviously the safer policy in instituting precautions in family practice is to assume that we have to deal with the more infective type of tuberculosis The preceding considerations enable us to conclude that phthisis is an infectious disease, that a certain personal vulnerability favours the disease, but that this vulnerability is widely distributed and may be acquired under unfavourable conditions of life, and that weight must be attached to the usually chronic course of phthisis involving repeated cumulative dosage of infection when certain simple precautions fail to be persistently and conscientiously carried out likely to be punctuated by the occurrence of infection than would otherwise have been the case. I regard the sanatorium training of consumptive patients, as distinguished from any pretension to cure, as the most important preventive measure which has hitherto evolved from our system of voluntary notification of phthisis in Brighton.

---

[2] Dr H T Bulstrode's Milroy Lectures THE LANCET, July 11th, 1903 p 75

[3] Ibid, p 76.

I do not propose to discuss the subject of compulsory notification of phthisis. It is certain to come, but there are strong reasons against "forcing the pace." The surest progress is gradual and preventive measures must be organised and elaborated before we can in most districts obtain much good from universal notification of cases. The Local Government Board has recently supported an enactment providing for the compulsory notification of phthisis in Sheffield on the understanding that the powers are confined to the enforcement of notification and of cleansing and disinfection. No powers of compulsory isolation of phthisical patients are conferred and no responsible person has so far as I am aware ever suggested or is likely to suggest that the granting of such powers is desirable.

I have endeavoured in the preceding remarks to indicate the ideal position of the medical practitioner in relation to tuberculosis. If my contention be correct it is equally true that therapeutical measures are in the widest sense measures of prophylaxis, and that the aid of measures of public and private hygiene is as indispensable to cure as are therapeutical measures. But the practitioner in the majority of cases—i.e., those of the working classes—can scarcely be said to be the "family" practitioner. Even in the higher social strata his efforts at prophylaxis may be hampered by prudential and other considerations and he cannot undertake those wider inquiries which are required in order most completely to stop the sources of infection. Clearly, then, everything indicates the necessity of coöperation between medical practitioner and medical officer of health, and the more complete is this coöperation the greater is the benefit to the consumptive patient and to every member of the public.

APPENDIX I.

PRECAUTIONS FOR CONSUMPTIVE PERSONS.

Consumption is, to a limited extent, an infectious disease. It is spread chiefly by inhaling the expectoration (spit) of patients which has been allowed to become dry and float about the room as dust, or by directly inhaling the spray which may be produced when a patient coughs.

Do not spit except into receptacles, the contents of which are to be [illegible] *dry. If this simple precaution is taken* [illegible] *of infection.* The breath of consumptive [illegible] except when coughing.

The following detailed rules will be found useful both to the consumptive and to his friends:—

1. Expectoration indoors should be received into small paper bags and *burnt* immediately; or into a receptable which is emptied down the drain daily and then washed with boiling water

2. Expectoration out of doors should be received into a suitable bottle, to be afterwards washed out with *boiling water*. If a paper handkerchief is used this must at once be placed in a waterproof bag, [illegible] rnt and the bag washed daily.

[illegible] if ever used for expectoration, should be [illegible] *e they have time to become dry*, or into a [illegible] directed by the doctor.

4. *Wet* cleansing of rooms, particularly of bedrooms occupied by sick persons, should be substituted for "dusting" and sweeping.

5. *Sunlight* and *fresh air* are the greatest enemies of infection. Every patient should sleep with his bedroom window *open* top and bottom, a screc [illegible] y, to prevent direct draught and the [illegible] bedroom.

N.B.—The pat [illegible] *ainer* by the above precautions, as his recovery is retarded and frequently prevented by renewed infection derived from his own expectoration.

6. Persons in good health have little reason to fear the infection of consumption. Over-fatigue, *intemperance, bad air, dusty occupations and dirty rooms favour consumption.*

APPENDIX II.

DEAR SIR,—I beg to inform you that   of
was admitted to the phthisis ward of the sanatorium on   and
discharged on   .

The following is a report of   condition:—

	On admission.	When discharged.
Weight...	—	—
Expectoration—		
(a) Amount	—	—
(b) Microscopically	—	—

General condition	—	—
Remarks	—	

The patient has been instructed to resume attendance under you.

Yours faithfully,

Medical Officer of Health.

NOTE ON THE PROBABLE MODE OF INFECTION BY THE SO-CALLED FILARIA PERSTANS, AND ON THE PROBABILITY THAT THIS ORGANISM REALLY BELONGS TO THE GENUS TYLENCHUS (BASTIAN).

By H. CHARLTON BASTIAN, M.D. LOND., F.R.S.,
CONSULTING PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

IN the reports of the Sleeping Sickness Commission, No. 3, recently issued by the Royal Society, Dr. Cuthbert Christy calls attention to, and illustrates by maps, the distribution of Filaria perstans in East Equatorial Africa so far as it was known up to Oct. 23rd, 1902, and shows how that area corresponds almost exactly with the area of "distribution of the banana cultivation and clothed people." The attire of the natives in these regions, as described by him, is so scanty and of such a kind as to make it difficult to suppose that the fact of its existence could favour infection of the natives by the nematoids in question. But great importance undoubtedly attaches to the striking similarity between the area of cultivation of the banana and that of the prevalence of Filaria perstans in East Equatorial Africa. The fact of this coincidence in area is all the more significant, seeing that the information supplied by Dr. Christy does not, as he says, favour the notion that mosquitoes are agents concerned with the causation and distribution of this disease. Dr. Christy says: "Wherever the banana is growing in the districts I have examined there is found the F. perstans. What is more, it would seem that where the banana is most luxuriant (on Mount Elgon) there the inhabitants are most infected (60 to 70 per cent. and the blood crowded). The converse of this is also clearly correct, as will be seen by the map—viz., where the banana is scarce (in Southern Bukedi and Northern Kavirondo, in which latter place it is only grown within the mud walls of the small villages) there the percentage of F. perstans is small; and where there is no banana there is no F. perstans." The uses to which the banana is put are thus referred to: "The banana when fully grown is peeled and boiled or steamed in an earthenware pot. The leaves are used for plates and dishes, for thatching houses, for clothing, for mattresses to sleep upon, for pipe stems, and many other things. The skins of the fruit are used for making soap, and the stems for rope, &c."

The author makes no allusion to, and perhaps may not be aware of, the fact that free nematoids are frequently to be found in the roots, stems, and leaves of plants, and that they are known to be found in the roots at least of the banana as it grows in Eastern Australia. The best known of the plants to be affected in this way are wheat, the common teasel, the feverfew, the cucumber, and the banana. In my "Monograph on the Anguillulidæ or Free Nematoids"[1] after referring to the mode of infection by wheat owing to the young nematoids passing from the earth in which wheat is growing, getting between the sheaths of its leaves and proceeding thence onwards to the immature germens, I say: "In several grasses I have found different species of these free nematoids lying between the inner sheaths of the leaves near the bottom of the culm. In Festuca elatior I met with no less than five species in this situation belonging to the genera Dorylaimus, Mononchus, and Plectus; and in the stalks of wheat and oats removed from stubble fields I have frequently found specimens either of these genera or of Rhabditis, Aphelenchus, or Cephalobus."

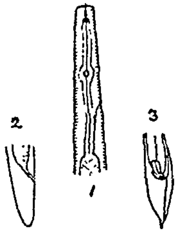
Many years since I ascertained that the nematoids which were to be found in the nodosities on the roots of certain cucumber plants in this country belonged to the genus Tylenchus and some years later (in 1879) I received an interesting pamphlet from Dr. Bancroft of Brisbane on certain "Diseases of Animals and Plants" from which I found that a very similar disease was common in Queensland among the bananas. From the merely rough figures there given of the worms it seemed to me evident that these nodose roots of the banana are also infested by nematoids of the genus Tylenchus. The females become so enormously distended with embryos that they assume somewhat the shape of a

---

[1] Transactions of the Linnæan Society, vol. xxv., 1865, p. 88.

Florence oil flask, so that Dr. Bancroft spoke of them as "flask-worms." I have found the mature worms, also assuming the same kind of shape in cucumber roots and from the same cause. Dr. Bancroft makes the following statements in regard to the occurrence of such worms in the roots of bananas: "The root of Musa maculata breaks off where the worm colony has been located; the sugar banana is more tolerant of the parasite and does not break off. This latter is the species of Musa which produces the fruit now sold in Brisbane." He found nematoids also in vine roots, in the roots of many culinary vegetables, and likewise in various weeds, particularly Sida retusa.

Sir Patrick Manson in his description of the embryo of Filaria perstans in Quain's "Dictionary of Medicine"[2] says, in regard to one of its distinguishing characters: "From time to time a minute tongue-like organ is rapidly protruded and withdrawn at the extremity of the cephalic end." A reference to Plate X., Figs 109, 112, 115, and 117 of my "Monograph [illegible] four species of [illegible] spear-like bod[illegible] genera of free nematoids in which bodies at all like this are met with are Aphelenchus and Dorylaimus. I reproduce drawings of the anterior and posterior extremities of one of these species of Tylenchus which was many years ago discovered by me in "sandy soil, about the rootlets of oats." This species has a blunt posterior extremity, such as is found in Filaria perstans, but in others it is sharp and pointed, as in the closely allied Filaria demarquayi.



Tylenchus obtusus. 1, Anterior extremity of worm. 2 Posterior extremity of female. 3, Posterior extremity of male. × 150 diameters.

The probability seems great, therefore, that the embryos found in the blood of human beings and known as Filaria perstans are really embryos of some species of Tylenchus; and further, as a species of Tylenchus has been found in Queensland by Dr. Bancroft infesting the roots of bananas, it seems quite possible, looking to the facts revealed by Dr. Christy, that a *nematoid belonging to the same genus* may infest the roots and perhaps different parts of the bananas in Equatorial Africa.

The modes in which the natives use the different parts of the banana [illegible] m to be infected either (1) thro[illegible] the alimentary canal. The fa[illegible] penetrate in some way through the skin—perhaps through the perspiratory ducts—is, I think, clearly shown by what is known concerning the parts of the body principally infested by Dracunculus. The evidence seems overwhelmingly in favour of this mode of infection, as originally suggested by H J Carter, and against a now commonly *received* view that the nematoids, through the intermediation of a cyclops, are taken into the alimentary canal with unfiltered water that has been drunk. It is quite possible that in some experimental investigations in which the young of the guinea worm were associated with these entomostraca, Fedschenko, the author of this latter view, may have seen young nematoids bore their way into the abdominal cavity of a cyclops, and yet his hypothesis as to the manner in which human beings become infected with guinea-worms may be wholly incorrect. As I long ago pointed out in a memoir on the guinea-worm[4] infection through the alimentary canal cannot reasonably account for the well-attested fact that in four-fifths or more of the whole number of recorded cases of guinea-worm the worms have been situated in the subcutaneous tissue of the lower extremities, and mostly below the knees, of persons who are in the habit of going about with bare legs and feet. The exceptions, too, are of a kind to prove the rule of external contamination, seeing that the Indian water-carriers, who bear on their backs water in eather bags or in skins, are not infrequently affected with guinea-worms in such exceptional situations as the back and the loins. Major Harrington of the Indian Medical Service, who has seen more than 200 cases of guinea-worm disease, is also firmly convinced that the views now commonly received are erroneous, and he has added further evidence in support of Carter's original view and direct external contamination.[5]

Although, therefore, I freely grant the possibility of such direct infection through the skin I think the evidence in regard to Filaria perstans points strongly to infection through the alimentary canal. The use by the natives of the banana leaves for "plates and dishes" would probably be one means by which infection could be thus brought about.[6] There is the further fact that in the cases where mature specimens of the so called Filaria perstans have been found, they have been situated not in the subcutaneous tissue in any part of the body but, as Dr. G. C Low says,[7] within the abdomen and "in the connective tissues of the mesentery." Without much difficulty we may imagine some of the young worms, taken into the stomach with food, boring their way through the intestinal canal after the fashion of embryo trichinæ and then, instead of wandering far, settling in the mesentery or in adjacent parts and there undergoing development. From such a situation it would be very easy for the young worms to pass into the lymph stream and thence into the blood.

I have thought it well to direct attention to the possible mode of infection and to the real nature of the organism hitherto known as Filaria perstans in order that those who have the opportunity may search for worms in connexion with the banana having the characters of Tylenchus, may ascertain whether *they are to be found in the fæces, and may* also look to the characters of the œsophagus and pharynx in any of the adult specimens of the so-called Filaria perstans that may be found in the mesentery.

My observations, as well as those of others, on the free nematoids have made it perfectly clear that a parasitic stage *forms no necessary* part of their life-history, though many of the forms may and do become parasitic in a more or less accidental manner—partly infecting various portions of plants and partly different tissues or organs of various animals. As facultative parasites, whether in animals or in plants, they commonly attain a very much larger size than that which characterises them in the free state, and instead of producing a small number of ova or embryos they commonly give birth to these in prodigious quantities. The most notable example of both these peculiarities is to be found in the guinea-worm.

Manchester-square, W.

NEW WORKHOUSE INFIRMARY.—The new workhouse infirmary for Swansea was formally opened on Jan. 18th in the presence of a large gathering. The building, which has taken about two years in construction, has been erected at a cost of £17,730.

THE OSIRIS PRIZE.—The *Electrical Engineer* of Jan. 22nd states that this valuable prize has just been divided between Madame Curie (in recognition of her part in the discovery of radium) and Professor Branly (inventor of the system of wireless telegraphy which bears his name). The prize is worth £4000 and was offered by M. Osiris in 1900 for any work which should be deemed useful for mankind by the members of the Syndicate of the Paris Press. The prize remained undistributed until it was recently suggested by the founder that the claims of the Curie family should be considered. It was then decided that Madame Curie should receive £2400 and that the remaining £1600 should go to Professor Branly.

A CONTRIBUTION TO THE AFTER-HISTORY OF GASTRIC ULCER.

BY JAMES W. RUSSELL, M.A., M.D. CANTAB., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE BIRMINGHAM GENERAL HOSPITAL.

THE majority of the histories recorded in this paper were collected a few years ago with the object of obtaining some definite information as to the ultimate ending of cases of gastric ulcer treated on medical lines—using the term "gastric ulcer" to include the various painful sequelæ as well as the actual continuance of ulceration. The inquiry was made in the hope that its results would be of service in pointing out the cases suitable for surgical interference and the stage, if any, at which it is fair to assume that medical treatment has finally failed to bring about a cure of the condition. I happened at the time to have under my care in the out-patient room an unusual number of cases of long standing and of very intractable nature, in which medical treatment both in the wards and outside had served only to procure temporary relief; and I was much impressed with the miserable mental and physical condition of the patients. On the other hand, the mortality of the operation of gastro-jejunostomy—at any rate at that time—was very considerable and it seemed to me to be a serious step to recommend so grave an operation unless the condition which it was intended to remedy either was one with a material death-rate of its own or involved permanent crippling of the life of the patient. I therefore tried to obtain some answer to the following questions: 1. What proportion of cases of gastric ulcer treated medically end ultimately in death apart from those which terminate fatally in the first attack? 2. What proportion end sooner or later in complete recovery? 3. What becomes of those cases which end neither in death, from the complaint nor in complete recovery? 4. At what point of the case may medical treatment be considered as having failed and what is the bearing of relapse on this question?

As I could not succeed in obtaining from medical literature any satisfactory answer to these questions, I gained the permission of my senior colleagues at the Birmingham General Hospital to follow up the after-history of the cases of gastric ulcer which had been treated in the medical wards of that hospital from the beginning of 1892 to the middle of 1899 and it is by their kindness that I am enabled to publish the results of the inquiry. My questions were sent out some three years ago and the near limit was fixed so as to give a minimum after-history of about two years. Any attempt to go further back than 1892 was found to be useless owing to the shifting character of the poorer population of this town. I have recently endeavoured to bring the inquiry up to date but have only succeeded in obtaining further particulars in 16 of the cases. Only female cases have been inquired into on account of the greater certainty of the diagnosis obtaining in women. Moreover, only those cases have been accepted in which there has been a definite history of hæmatemesis and, with one exception, the date of the first hæmorrhage has been taken as that of the onset of the disorder. I am, of course, aware that the mere occurrence of hæmatemesis, even when accompanied with gastric pain and vomiting, is not conclusive proof of the existence of an ulcer, and it is, moreover, highly probable that in many of the cases ulceration had taken place some time before the occurrence of hæmorrhage. But worse fallacies would probably have been involved in any other method of selection.

During the seven and a half years covered by my first inquiry there were admitted into the medical wards of the hospital 89 women with hæmatemesis diagnosed as due to gastric ulcer, excluding the cases ending fatally in the first attack—the indications for surgical treatment in the latter being already well established. Of these 89 cases I succeeded in tracing the after-history of 47 and of 16 I have recently obtained further particulars. The length of time over which the histories extend varies within wide limits and the value of the results necessarily diminishes with the shortening of the period covered. Starting from the first hæmatemesis the length of the cases has been as follows: from two to three years, 12 cases; three to four years, five cases; four to five years, nine cases; five to six years, seven cases; six to seven years, three cases; seven to eight years, two cases; eight to nine years, one case; nine to 10 years, three cases; 10 to 11 years, two cases; and 12 to 13 years, three cases.

1. *Mortality* (Cases 1 and 2).—At the time at which the main inquiry was made two deaths only had occurred, though a third patient died in hospital from ruptured pyosalpinx a few months after answering my questions and was found post mortem to have an extreme hour-glass contraction of the stomach. Of the two former deaths, one only was directly due to the gastric ulcer—whether from perforation or not I cannot say, the note merely stating that the patient had died from "a return of her former complaint." The second patient died from acute tuberculosis four and a half years after her hæmatemesis, but I have no information as to the continuance of gastric symptoms in the interval. No further death was recorded in the 16 cases of which I have obtained recent particulars. The direct mortality from gastric ulcer has therefore, as far as my information extends, amounted to only 2 1 per cent. But it would of course be altogether *inaccurate to represent this as the final mortality of the* series, for the length of history in a large number of the cases is insufficient to warrant any conclusion as to their ultimate ending. Moreover, the fact of death may quite possibly be one element in causing the disappearance of the untraced cases, and the mortality in these may therefore not improbably amount to a considerably larger figure. It occurred to me, however, that if any material proportion of these untraced cases had died directly from the effects of their disease a record of some, at least, would probably be found in the registers of the other hospitals of the town. But no such record was forthcoming. By the courtesy of the staff of the Queen's Hospital I was permitted to examine the in-patient register of that hospital, with the result that I did not find the names of any of the 42 untraced patients amongst either the admissions for, or the deaths from, gastric ulcer. I have also searched the surgical register of the General Hospital and have been allowed to examine the record of deaths occurring in the Birmingham Workhouse Infirmary, with the same result. Yet the disasters of gastric ulcer are of so urgent a nature as to lead to admission into hospital to an extent probably out of proportion to their actual frequency and I cannot but think that if death were a common result some at least of the untraced patients would have died in one or other of the public hospitals of the town. It must, however, be remembered that I am dealing exclusively with patients of the female sex and that marriage, with its consequent change of name, is one possible cause for loss of identity. It is further worth noting that out of 6040 deaths occurring in the workhouse infirmary from 1892 to 1901 only two were attributed to gastric ulcer. There were, of course, other deaths from "peritonitis," and it is possible or probable that some of these may have been due to the perforation of a gastric ulcer, especially as post-mortem examinations had not, I believe, been made in all the cases. But it seems clear at all events that gastric ulcer is not a frequent cause of death in the institution and the net result of my inquiries is to show that, apart from first attacks, the disorder is one with but a small mortality.

2. *Recovery* (Cases 3 to 15).—13, or 27·7 per cent, of the patients, reported themselves as having had no return of their complaint. One, however, remarked that she was still liable to indigestion if she took improper food and another is seldom able to take meat without discomfort. The period of immunity has been as follows: from two to three years, two cases; three to four years, two cases; four to five years, four cases; five to six years, three cases; six to seven years, one case; and seven to eight years, one case. Seven other patients, or 14 9 per cent., suffered from stomach symptoms of some severity or from definite relapses for periods after their first attack varying from a few months to six years, but had remained in good health when the last report was obtained for a sufficient length of time to justify their inclusion in the class of recoveries. The histories of these patients are of especial interest from their bearing on the question of recovery after relapse. I therefore give their reports in detail.

Duration[1] *five to six years.*—Case 16. Admitted for hæmatemesis, October, 1898. "Always in pain" (December,

---

[1] From first hæmatemesis to last report.

1900). "No further attack and am now in good health" (December, 1903). Case 17. Hæmatemesis, April, 1898. Admitted for pain and vomiting, October, 1898. "Three slight attacks in autumn of 1899, spring of 1900, and October, 1900." No further return (December, 1903).

Duration six to seven years.—Case 18. Admitted for hæmatemesis, May, 1897. "One attack, February, 1898. Since in good health" (December, 1903). Case 19. Admitted for hæmatemesis, October, 1897. "Several attacks of sickness for three months after leaving hospital. No further return" (December, 1903).

Duration nine to ten years.—Case 20. First hæmatemesis, 1891; second, July, 1894. Out-patient for pain and vomiting, November, 1897, and May, 1898. "Now in good health" (December, 1900).

Duration 10 to 11 years.—Case 21. Hæmatemesis, 1890. Admitted with pain but no hæmorrhage, January, 1892. No further return (December, 1900).

Duration 12 to 13 years.—Case 22. First hæmatemesis, 1891. Admitted with relapse and hæmorrhage, July, 1893. "Three further attacks in next two and a half years. Since in good health" (December, 1903).

One other patient (Case 23) technically comes under this heading inasmuch as she is now free from all stomach symptoms though suffering for several years after her discharge from the hospital. But her inclusion is inadmissible owing to the performance of an operation—possibly gastro-jejunostomy—four or five years ago. She was admitted into hospital for hæmatemesis in October, 1894. In December, 1900, she reported that she had "suffered severely with her stomach since," that an operation had been performed in 1899, but that she was "now suffering and unable to work and could not digest any solid food." In December, 1903, however, her medical attendant informed me that she had completely recovered and was now free from all gastric symptoms. In this case the connexion between the operation and recovery is by no means established but it is only fair to add that I have not been able to satisfy myself from the hospital records that the operation of gastro jejunostomy was certainly that which was performed. Omitting this case from the calculation it will be seen that in the other seven the periods of immunity have amounted at the time of the last report to from two to three years in two cases, from three to four years in one case, and from five to six and six to seven years in two cases each. Accepting these cases as cured there is therefore a total of 20 recoveries, or 42·6 per cent.

3. *Doubtful cases.*—Three cases, or 6·4 per cent., are difficult to classify. The patients have all suffered from stomach symptoms since their discharge with periods of more or less complete immunity, but either the interval since the last attack has not been of sufficient length to afford ground for any definite conclusion as to the ultimate results or the evidence of recovery given is unsatisfactory. The reports are as follows:—

Duration two to three years.—Case 24. First hæmatemesis, 1898. Admitted with relapse and hæmorrhage, June, 1899. No further return but still gets occasional attacks of "bile" (December, 1900).

Duration five to six years.—Case 25. Admitted for hæmatemesis, January, 1895. Readmitted for relapse without hæmorrhage, March, 1898. "Very sharp attack, April, 1899, which left her very weak for some time and slight attacks in between. Now fairly well" (December, 1900).

Duration 10 to 11 years.—Case 26. Hæmatemesis, 1889. Admitted with relapse and slight hæmorrhage, December, 1894. "Very ill in 1896 and slight attacks since, but at present time feeling stronger" (December, 1900).

4. *Non-recovery.*—The remaining 21 patients, or 44·7 per cent., reported themselves as still suffering from their complaint. In the first seven cases there were repeated attacks of pain and vomiting, with or without hæmatemesis, but with intervals of comparative immunity.

Duration two to three years.—Case 27. Admitted for hæmatemesis, September, 1898; remained well for six months. Then readmission for severe hæmorrhage. Second relapse, but without hæmorrhage, October, 1900. This patient died from ruptured pyosalpinx and was found to have hour-glass contraction of the stomach. Case 28. Admitted for hæmatemesis, November, 1898. Remained fairly well till beginning of 1900. Readmitted March, 1900. Frequent attacks since August (December, 1900).

Duration four to five years.—Case 29. Admitted for hæmatemesis, May, 1899. Readmitted with relapse and hæmorrhage, March, 1901. Two or three attacks since (December, 1903). Case 30. Admitted with hæmatemesis, April, 1899. Three slight attacks in latter part of 1900 and beginning of 1901. Two "bad attacks" in July, 1901, and October, 1903. Case 31. Admitted with hæmatemesis, March, 1896. In workhouse infirmary with hæmorrhage, 1897, and remained there for 17 months. Out-patient with relapse, January, 1900.

Duration seven to eight years.—Case 32. First hæmatemesis, 1896. Admitted with relapse and slight hæmorrhage, March, 1898. Three subsequent attacks, three weeks after leaving hospital, November, 1898, and March, 1900. Now in good health (December, 1900). "Complaint returns every winter. At hospital with same complaint last November" (December, 1903).

Duration nine to ten years.—Case 33. First hæmatemesis end of 1894. Admitted February, 1895. Readmitted for hæmorrhage, July, 1898. "Still suffering from pains in stomach" (December, 1900). Third hæmatemesis, 1901, and "still gets occasional attacks of vomiting with intense pain" (December, 1903).

The remaining 14 patients were suffering more or less continuously.

Duration two to three years.—Case 34. Admitted for hæmatemesis, April, 1898. "Never lost the pain since, but no more hæmorrhage." Last seen October, 1900, with bad attack of pain and vomiting. Case 35. Admitted for hæmatemesis, October, 1898. "Continuously bad since leaving hospital. Sickness every day except for first six weeks" (December, 1900). Case 36. Admitted for hæmatemesis, October, 1898. Pain and vomiting at intervals for next year, with readmission for second hæmatemesis. "Several attacks since leaving hospital and never well for long." Out-patient with recurrence of pain, November, 1900, and again in April, 1901. Case 37. Admitted for hæmatemesis, November, 1898. "Two attacks since leaving hospital and just out of Homœopathic Hospital. Has suffered a great deal of late and is unable to follow her employment" (December, 1900). Case 38. Admitted for hæmatemesis, November, 1898. "Complaint returned a week after leaving hospital. The attacks have been so frequent that she could not say how many she has had" (December, 1900). Case 39. Admitted for hæmatemesis, January, 1899. Two attacks since leaving hospital in January and July, 1900. Has been under out-patient treatment "suffering great pain and does so now" (April, 1901). Case 40. Admitted for hæmatemesis, February, 1899. "The attacks are very frequent. Can only keep very small quantities of milk on her stomach" (April, 1901).

Duration three to four years.—Case 41. Admitted for hæmatemesis, February, 1897. "No return, but has been a great sufferer from indigestion and is now under treatment" (December, 1900).

Duration four to five years.—Case 42. Admitted for hæmatemesis, July, 1896. "Moderate pain on and off since leaving hospital. Last week or two, increase in pain" (December, 1900). Case 43. Admitted for hæmatemesis, March, 1899. "Fairly well for the first 12 months, but since has felt very bad and sick about every fortnight. Has had a turn lately" (April, 1901). "Still keeps very bad" (December, 1903).

Duration five to six years.—Case 44. Admitted for pain without hæmorrhage, 1895. "Continuously bad since." Readmitted for profuse hæmorrhage, January, 1900, and again admitted, December, 1900, with bad pain and doubtful slight hæmorrhage. "Life not worth living."

Duration eight to nine years.—Case 45. Admitted for hæmatemesis, February, 1895. Second hæmorrhage, July, 1896, and readmission with pain, November, 1896. Then

nine months in

into Homœopa

there for 16 we

last three years,

ment at the hospital" (December, 1903).

Duration 12 to 13 years.—Case 46. Probable slight hæmatemesis, 1891 or 1892. Admitted for severe pain, October, 1893. Readmitted, February, 1894, and October, 1896, the latter time for hæmatemesis. "A good many attacks since then" (December, 1900). "Still frequen pain and vomiting. More hæmorrhage three weeks ago" (December, 1903). Case 47. First hæmatemesis ab 1889. Further attacks, but without hæmorrhage, 1 and 1895. Admitted with pain and vomiting, Decem 1896. "Several attacks since leaving hospital. Bad a with hæmorrhage four months ago" (December, 1900). "Not been free from her complaint for any length of time. Now under treatment and is told that she is in danger of a relapse" (December, 1903).

To sum up, the result of the inquiry is as follows. The direct mortality from the disorder has amounted to 2·1 per cent. 4·3 per cent. of the patients have died from intercurrent disorders, one of them with serious organic disease of her stomach. 42·6 per cent. have ended in recovery—unless the subsequent history disproves the statement—27·7 per cent. having had but a single attack and 14·9 per cent. having recovered after one or more relapses. One patient recovered after operation but is not included in the calculation. 6·4 per cent. of the patients cannot as yet be classified; they appear to be on the border-line between recovery and continuance of the disorder and may eventually fall into either class. Finally, 44·7 per cent. were suffering from stomach symptoms of more or less severity at the time of the last report, 14·9 per cent. getting repeated and definite attacks with intervals of immunity and 29·8 per cent. suffering from almost continuous pain. It would be unwise to attempt to draw any definite conclusion as to the number of cases in the last group in which it would be advisable to recommend surgical interference. In all probability some of the patients will ultimately recover, whilst it is quite possible that a direct examination of others would show that their reports have erred on the side of exaggeration. In others, again, the amount of suffering appears to be comparatively small. But on the whole, I am inclined to think that the group affords some justification for the plea often made in favour of more frequent resort to operative interference in persistent cases of gastric ulcer, always providing that the mortality of the operation can be kept at a really low figure and that the results in the cases operated on can be shown to be permanently good. But at the present time further evidence on both these points seems to me to be needed.

5 *Bearing of relapse on recovery.*—It will be remembered that seven patients suffered from continuance of their symptoms for some time after leaving the hospital but had remained in good health for periods amounting to two or more years at the time of their last report. In two of these there was a second hæmorrhage; in the others it is either clear that no further hæmorrhage had taken place with the recurrence of symptoms or the report is indefinite on the point. Of the three border-line cases hæmorrhage recurred in two and in the third is uncertain. On the other hand, of the 21 cases of non-recovery a further hæmorrhage took place with certainty in nine whilst in a tenth case the history of the second hæmorrhage is not quite trustworthy. In two of the cases a third hæmorrhage is recorded. Of the 13 definite instances of recurrent hæmorrhage, therefore, only two are included in the list of recoveries. It thus appears that whilst a second hæmorrhage by no means precludes recovery it is a serious factor in prognosis, pointing at least to a considerable prolongation of the period of active symptoms.

The following list gives the intervals between the first and second hæmorrhages Recoveries: from one to two years, one case; and from two to three years, one case. Non-recoveries: under one year, two cases; from one to two years, five cases; and from three to four years, two cases. Finally, the period over which symptoms continued to recur in the seven cases of ultimate recovery has been as follows: three months, one case; nine months, one case; from one to two years, one case; from two to three years, two cases; from four to five years, one case; and from seven to eight years, one case.

Birmingham.

Queen Charlotte's Lying-in Hospital, Marylebone Road, N.W.—Madame Melba has promised to sing at a concert in aid of Queen Charlotte's Hospital to be held at Queen's Hall on the afternoon of Thursday, May 5th.

Education of Town Children in Village Schools.—Mr O. C. Lempriere of the Red House, Marston Moor, York, has sent us a pamphlet in which he suggests that children of the poorer classes at present educated in the schools of the large towns should be sent to the country for 10½ months of every year Mr. Lempriere thinks that physical, mental, and moral advantages would result to the child if this scheme were adopted, while the consequent building up of the national health, physique, intelligence, and *morale* would be an advantage to the State.

NOTES ON A CASE OF OTITIC CEREBELLAR ABSCESS; EXTRADURAL ABSCESS; TREPHINING MIDDLE AND POSTERIOR FOSSÆ; RECOVERY.

By PERCY JAKINS, M.D. Durh.,

SURGEON TO THE CENTRAL LONDON THROAT AND EAR HOSPITAL

A girl, aged 12 years, attended the out-patient clinic of the Central London Throat and Ear Hospital on June 15th, 1903, complaining of offensive purulent discharge from the left ear, accompanied by severe pain over the left mastoid and in the posterior triangle, nausea, vomiting, and vertigo of four days' duration. The patient was admitted at once as an urgent case and the following history was elicited. The discharge had followed scarlet fever nine months previously. There had been no decided pain till four days previously. The left meatal canal was found to be filled with a yellowish-green offensive discharge which when removed revealed granulations. There were partial right facial paralysis, slight want of grip in the right hand (the patient was right-handed), both knee-jerks were exaggerated, the left pupil was dilated, there were left optic neuritis and drowsiness, the tongue was foul, the temperature was subnormal (97·2° F.), and the pulse was 72. There was a distinct tuberculous history but no specific treatment had been adopted. On the following day (the 16th) the patient was placed under chloroform and the part having been shaved and rendered aseptic a semilunar incision was made over the left mastoid from the lower border of the temporal muscle to the apex of the mastoid; the periosteum was then reflected and the cartilaginous part of the meatus was separated from the osseous. The ear having been drawn forward the antrum was explored and was found to contain granulation tissue; this was curetted and a purulent discharge was seen issuing from a small aperture in the upper and posterior part of the antrum. This wound was enlarged and about a teaspoonful of very offensive pus was liberated; the bone around, which was very soft and carious, was freely curetted. During the next five days the patient improved considerably, the nausea, vomiting, and vertigo partially subsiding and the morning temperature falling to normal and the evening to subnormal. On the 22nd the discharge from the mastoid became very offensive, the patient getting drowsy; her head was retracted, the lips were parted, the pupils were dilated, especially the left, the grip in the right hand was feeble, cerebration was very slow, the tongue was very foul, the temperature was 98°, the pulse was 60 and intermittent, and the respirations were 24 On the next day the symptoms were more defined; the patient could not speak, was unconscious except when pinched, and could not understand what was said; the right hand was absolutely helpless, the hands were cold, and the head was hanging over the edge of the pillow. On the 24th the former mastoid incision was reopened and more carious bone was removed from the roof of the antrum, but no pus was found coming from the former situation. The skin incision was then carried upwards, the temporal muscle was divided, the periosteum was reflected, and a piece of bone was removed by the trephine, these procedures causing rather severe bleeding. On removing the disc of bone the dura mater was found to be very tense, bulging into the trephine opening, but there was no pulsation; the dura mater was divided and a long thin knife was passed into the cerebral tissues. No pus was found and serous fluid escaped freely The bulging of the cerebral tissue into the trephine opening resisted all efforts at replacement. It was now decided to explore the posterior fossa. A curved incision was made through the scalp down to the bone, one and a half inches behind and a quarter of an inch below the centre of the external auditory meatus. A disc of bone was removed by the trephine exposing the dura mater; this had a healthy appearance; it did not protrude but pulsated distinctly. The dura mater was divided and a long thin knife was passed inwards and upwards in the direction of the original opening in the posterior antral wall with the result that pus of a very fœtid kind flowed over the knife. A Horsley's pus seeker was next used and the abscess cavity was entirely emptied of its contents to the extent of about 12 drachms of pus. The point to be here noticed is that as soon as the pus was evacuated the protrusion of the brain substance into the opening of the middle fossa subsided and pulsation reappeared. Fine catgut sutures were used to stitch the dura mater in the temporo-sphenoidal opening, three medium-sized drainage-tubes were inserted into the opening into the posterior fossa, and the superficial tissues were all stitched up. On the next day the patient was quite conscious, talking and answering questions at once, the grip in the right hand improved, there was no nausea or vertigo, and the paralysis of the limb was gone. The pupils were still dilated, the temperature was normal, the pulse was 88, the respirations were 22, and she wished to eat and to read. The discharge being abundant the patient was advised to lie on the affected side so as to aid drainage. On July 1st the stitches were all removed and the opening of the temporo-sphenoidal region was perfectly healed. On the 15th exuberant [illegible] ring with free drainage; this [illegible] ([illegible] an anæsthetic) and the tubes were re-inserted; this secured better drainage and for the next ten days the patient was very well; there was no paralysis, nausea, vomiting, or vertigo; she ate and slept [illegible] was absolutely [illegible] was regular, [illegible] patient complained of slight headache and nausea; the temperature was subnormal and the pulse was 98, but on regulation of diet and attention to the primæ viæ these symptoms disappeared and she was sent to the Royal Free Hospital as the wards of the hospital were closed for the annual cleaning. She was discharged from the Royal Free Hospital the following week, all symptoms having disappeared except the facial paralysis and slight discharge from the external meatus. On August 13th a slight fluctuating swelling was noticed over the posterior fossa opening, which on being incised let free a little pus which appeared superficial. On Sept. 6th the patient for the last three weeks had had slight oozings from the opening that was made on August 13th. She seemed to be quite well but was not gaining flesh; the temperature was subnormal and the pulse was slow. She was readmitted into the Central London Throat and Ear Hospital and on Sept. 8th it was decided to explore the posterior fossa and on re-opening the wound and incising the thickened dura mater about one ounce of purulent pus was evacuated. One large drainage-tube was inserted and removed and cleansed every day. The drainage-tube was gradually shortened and on Nov. 2nd it was left out altogether. On the 13th the patient was discharged cured, facial paralysis being the only symptom left.

This case shows the advisability, in cases of suppuration of the middle ear which do not yield rapidly to treatment, of the radical operation being seriously considered, not only with a view of arresting the discharge from which the patient suffers but to prevent deeper mischief, such as cerebral abscess. During the last few years I have operated upon four cases of cerebral abscess caused by extension of mischief from the middle ear. For the full notes of the foregoing and for the necessary after attention upon the patient I am indebted to my colleague Dr. A. Wylie.

Harley-street, W.

THE EFFICIENT TREATMENT OF CARDIAC FAILURE.[1]

BY ALEXANDER MORISON, M.D. EDIN.,
F.R.C.P. LOND. & EDIN.,
PHYSICIAN TO OUT-PATIENTS AT THE GREAT NORTHERN CENTRAL HOSPITAL; PHYSICIAN TO THE CHILDREN'S HOSPITAL, PADDINGTON-GREEN.

IT has been told of a late distinguished physician that having met a practitioner in consultation on one occasion who had failed to discover a pericarditis, and who was somewhat chagrined thereat, he told him he might console himself as, had he discovered it, he might have attempted to treat it. Had this great physician's praise of therapeutic inactivity ceased with this narrative it would have been well, but he exalted the wisdom of doing nothing in the presence of imperfect knowledge to such a pitch of virtue that the profession of medicine as distinct from surgery was largely reduced within the sphere of his influence to rational attempts at diagnosis and prognosis, the inculcation of a moderate life, and the supervision of esculents, all doubtless very important considerations in their own place, as everyone knows. It is true that in many departments of medicine our knowledge is still so imperfect, and must probably for long remain so, that we have still to step in the house of life with gentle tread in these regions, but there are also many contingencies with which we have to grapple in which life is lost by the baneful influence of a timidity in therapeutics begotten of a pessimistic *non possumus* emanating from some authoritative source and paralysing for a time at least the therapeutic activity of considerable sections of the profession. Masterly inactivity has its place, but so also has fighting to a finish, be it in victory or in defeat.

There is no department of medicine over which the physician has more control than that which holds diseases and disorders of the heart, and it is in this sphere that I wish to preach a greater, yet always circumspect, boldness of treatment than at times obtains. By heart disease in this connexion I mean all conditions of the central organ of circulation which directly or indirectly, immediately or remotely, sometimes or often, threaten the extinction of human life. It follows from this definition that the emergencies we have to contend with may be (1) of an acute, rapidly arising, and sudden character; and (2) of a chronic nature and acquiring, as we may term it, an ingravescent urgency. Both kinds must necessarily be associated with cardiac failure, threatened or accomplished, which may or may not end in death—an event only too commonly observed in these circumstances. The scope of our subject and the limits of time will preclude its detailed consideration, but I shall, I trust, be able to lay before you a sufficiently comprehensive survey of the whole matter.

It is not my intention to burden the text of this paper by narrating cases but to emphasise the value of boldness as a principle or line of conduct in the treatment of heart disease, in certain typical circumstances, all precautions being taken to render a bold initiative likely to succeed and not to be more disastrous than the grave and respectful witnessing by the expectant physician of the practically unaided attempts of life to escape from the grasp of death. Any occasion for a rational boldness of conduct implies some urgency in the situation to be contended with. In using the term in connexion with the treatment of heart disease it is, of course, not my intention to urge that we should declare ourselves foolish by rushing in with a multifarious armamentarium where the wise would fear to tread but to lay before you some considerations which I hope will be freely discussed and which have been borne in upon me by my own experience and a study of that of others—that is, by my own failures and successes and a consideration of those of others. This has impressed me with the belief that while it may often be our duty to change our methods, and even to retreat from a given line of attack, there are circumstances when such a strategic movement towards the rear may seem highly advisable, but in which, nevertheless, the only possibility of saving the patient consists in our going boldly forward with all the forces at our command and pressing the attack quite home; in which, in short, the cartridge has to be cast aside and the enemy's entrenchments cleared with the bayonet if possible. Indeed, to continue our military metaphor, when brought face to face with any case of heart disease we must of necessity in the first instance reconnoitre the threatened danger carefully and learn what we can of its nature. We must endeavour, in other words, to make a correct diagnosis and to estimate aright, so far as possible, the conditions of the neural, muscular, hæmic, and mechanical factors in the action of the heart and the relation of that constantly acting organ to surrounding parts. We may find on examination so little amiss that the enemy, instead of being boldly attacked, may merely require to be kept under observation, or even ignored. Before doing this, however, we must be certain, if possible, that a more serious, and it [illegible] trivial [illegible] resem- [illegible] matism bling those of [illegible] revealed their true nature by an which have suddenly [illegible] and it may be fatal angina onset of unmistakeable [illegible] pectoris. Such signs after middle age or in advanced life should never, especially in the presence of signs of organic lesion, be dismissed as trivial even though the ignorant may regard us as alarmists. On the other hand, even in the presence of gross disease, if we can satisfy ourselves that with all the signs of disease in the cardiac mechanism present the evidences are absent of any serious disturbance of the innervation, muscular force, or blood distribution of the case before us, it may be our duty to advise a continuance of even strenuous exertion, to avoid that mental dissolution of energy to which cardiac patients are peculiarly prone. In acting thus it is quite possible that the ignorant who at one time regarded us as alarmists may now consider us rash. But the force of criticism depends upon its source and those only who have smelt a good deal of powder can speak with weight of the conditions of battle. It may require some boldness in practice to lay a man by the heels in bed who imagines he is fit to run a race and to send another on a journey who imagines he ought to go to bed, but this is not the chief form of boldness in the treatment of heart disease with which we have to deal this evening, although these are considerations which must be mentioned in discussing the efficient treatment of cardiac failure.

---

[1] A paper read [illegible] The portion dealing [illegible] West London Medi [illegible] title "On Boldness [illegible]

The danger which threatens life from heart disease may, as I have remarked, be of unexpected and sudden origin and may have to be met by the physician with the promptitude which characterises the surgeon's action in dealing, for example, with an obstructed trachea or a severed blood vessel. Or it may be more or less remote or ingravescent in its urgency, when the physician, like the surgeon contemplating an unavoidable but not immediate operation, has time to observe his patient and to prepare him for the ordeal. This similarity of the situation of the surgeon and physician in these circumstances is one which I desire to emphasise this evening. The surgeon knows his instruments and the anatomy of the patient and has confidence in his power in a large proportion of cases of coming to the rescue with beneficial effect. Let us also, as physicians, in dealing with accomplished or threatened cardiac failure imitate the precision and cautious boldness of his methods instead of preaching the doctrine of a depressing therapeutic pessimism and uttering platitudes concerning the inscrutability of natural processes, or by action inscribe ourselves on the roll of the disciples of that popular professor the late Mr. Micawber of expectant memory, and we shall find both the utility of our endeavours and the dignity of our office enhanced. No more than the surgeon can the physician be invariably successful; but let us, like him, by the forethought of our preparations and the skilful use of the powerful agents we, like him, possess, act when occasion arises with all the trenchancy, boldness, and hopefulness which the conditions involved permit and we may deserve the success we cannot always command. You will not expect me, for it would within the limits of our time be an impossible task, to deal fully with the etiology of cardiac failure and to set forth at length the factors which determine our action in particular instances, but there are some considerations which must, however cursorily, be mentioned in any rational consideration of so important a topic as the management of serious heart disease.

We are all aware that when the contractile efforts of the heart removed from the body—the eviscerated heart—begin to fail they may be urged to fresh vigour by stimulants applied to the organ. We also know that the rapidity with which the irritability of the cardiac muscle responds to such stimuli bears some relation not only to the state of the muscle fibre but also to the shock preceding the evisceration of the organ and conveyed to it through the nervous system or to the nature of some poison causing death which has reached it by the channel of the blood. I do not wish you to conclude that my knowledge of the effect of shock on the heart is based upon what the prejudiced and ignorant critics of scientific inquiry term ruthless vivisection for the satisfaction of scientific curiosity. For although the most precious possessions of mankind have come to them, with the sanction of an all-wise Creator, through the medium of one or other form of sacrifice or suffering justified by the greater good accruing, he libels us, at times fortunately to his very material cost, who accuses us of inflicting wanton suffering on dumb animals to wrest even a valuable secret from nature.

My own knowledge of the effect of shock on the eviscerated heart is based upon experience, not in what "our friends the enemy" term the shambles of the physiological laboratory, but in shambles where Gog and Magog prepare the Gargantuan feasts of which the antivivisectionist has doubtless on many occasions been a proud participant. However observed, it may be assumed as fact that, given a tolerably active muscle, the extinction of its irritability bears a direct relation to the shock of disease or injury which precedes cardiac failure. It is more easy, therefore, other things being equal, to revive the unshocked than the shocked heart which has failed, and for the same reason the sudden overthrow of a heart by, for example, the rupture of a valve is a more dangerous event than the gradual extinction of its power by slowly established and progressive disease. In proportion to such degree and urgency of failure must be the always circumspect and cautious but nevertheless necessary promptitude and boldness of our own endeavours to relieve or to save, provided the physical conditions involved admit of the display of boldness without aggravating the situation.

The object of these preliminary remarks is that in dealing with any case of cardiac failure we must bear in mind the predominance of the rôle which may be played by one or other, or by one or more, of the four factors in cardiac action already mentioned—namely, the neural, the muscular, the hæmic, and the more purely mechanical factors in such action, and by our estimate of the nature and gravity of their disorder be guided in the choice of bold action or alert observation. In the first place let us consider shortly the influence and management of disorder of the *neural* factor.

Cardiac failure to a profound degree may be observed without pain but not necessarily without shock. The profound syncope, for example, attending violent explosions of epilepsy cannot be dissociated from shock, although it is the shock which attends surgical operations under anæsthesia, for the cerebral cortex is placed out of action by the vascular mechanism which produces the fit before the actual convulsions occur. Again, in debilitated states slight exertion or excitement or a minimum of suffering may have the same effect, the resulting phenomena being to all intents, though for a time only when recovery takes place, those of death. During such a phase of cardiac failure, whatever other agents we may use such as nitrite of amyl, atropine, or strychnine, we must promptly endeavour to rescue the patient by the employment of artificial respiration with forcible expiratory compression, which succeeds in proportion to the resiliency of the thorax, or by this means in conjunction with firm but careful and rhythmical tongue traction. Experience alone can fully impress one with the value of these methods in these circumstances. But a still more dreaded expression of disorder of the neural factor in cardiac failure is that attending cardiac shock when the cortex is in full activity. The dead heart of angina pectoris is a flaccid diastolic heart, the failure of which may be progressively determined by auscultation during the agony. In such cases rescue, when possible, is only to be effected by the prompt use of the rapidly acting nitrites, and failing these by the sufficient employment of morphine and atropine, or by these combined if need be with volatile anæsthetics. The late Dr. George Balfour of Edinburgh, the keynote of whose methods in the treatment of cardiac failure was one of boldness and who would not have lived in vain had he done nothing more than preach this doctrine, used large doses of morphine and even induced complete anæsthesia by chloroform in these circumstances. It may be necessary here also to employ artificial respiration and tongue traction, but the anginous patient requiring this manœuvre is usually past remedy. The future probably holds some still bolder method as a last resource which professional opinion is not yet ripe to approve. Many of you must have read with interest the account published in THE LANCET[2] of Mr. Arbuthnot Lane's successful restoration of a heart to action which had failed during an operation for appendicitis by passing his hand through the wound and grasping it through the diaphragm and thus stimulating it into renewed action. Just as we find we can rouse the eviscerated heart to contraction by manipulation, so Mr. Lane in this case roused the heart which had recently ceased to beat into fresh life. Such an experience, rendered possible by the study of life in the lower animals, is a fact which the reasonable antivivisectionist might well ponder, if such a being is to be found. It is difficult even with a flaccid abdomen to reach the heart adequately through the epigastrium, but it is well to attempt it, and it is certainly likely to be quite as successful as any pin-prick of the organ by acupuncture through the chest wall and is less likely to do mischief. It would be well always to add this manœuvre to the other details of artificial respiration during the expiratory phase. What I have said as regards the treatment of the shock attending cardiac pain applies likewise to that attending rupture of the valves or the condition so often simulating this—namely, a sudden rupture of established compensation in chronic valvular disease.

---

[2] THE LANCET, Nov. 22nd (p. 1397) and 29th (p. 1476), 1902.

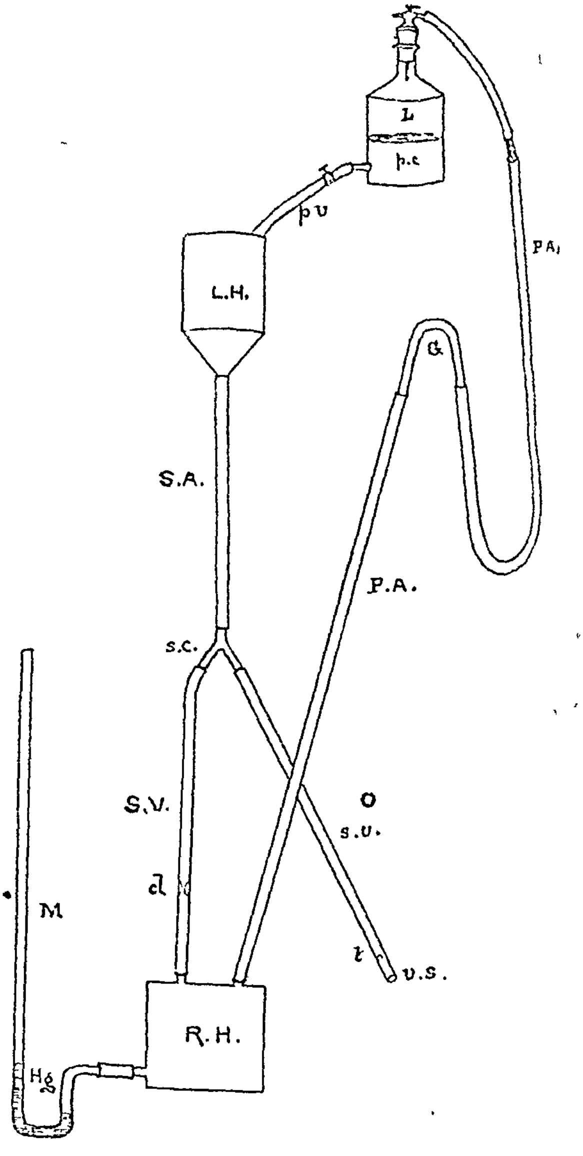
There are other neural accidents of a less urgent character which unchecked may lead to a fatal issue to which I might refer but the time at our disposal is short. I may, however, mention the tachycardia which may overtake a tolerably well-compensated heart affected with valvular disease. In such cases there are two agencies the value of which has been impressed on me by experience. The most important of these is opium in sufficient doses. The other is ice. This may be applied to the head, nucha, or præcordia with such continuousness as the state of the patient may permit. Dr. J. Barr of Liverpool appears to have found ice most useful as a vaso-motor stimulant (or sedative according as we may regard it) when applied to the abdomen. There are theoretical reasons which render the success of this procedure probable.

In considering the efficient treatment of the *muscular* factor in cardiac failure we have to deal with a subject of the greatest practical interest. By the muscular factor on this occasion I mean the cardiac muscle particularly and exclude from consideration the influence of the general musculature of the body upon the circulation, a detail which is of importance chiefly in less urgent phases of cardiac failure than those in which a judicious boldness in treatment is usually called for. A patient is before us with the evidences of progressive cardiac failure. He is dyspnœic in various degree, his cardiac area of percussion dulness is increased, he shows the evidences in the heart, and it may be in other organs, of the effects of a residual accumulation of blood within the chambers of the heart, right or left, or both right and left. We put him to bed, unload his primæ viæ, take into consideration his age and the general state of his vessels and other organs, as well as the particular condition of his heart endocardially, myocardially, and pericardially. Finding, as we unfortunately do in many cases, that rest, dietetics, and general care have, unaided, little effect on his state we try the influence of small doses of the infusion or tincture or powder of the well-known pharmacological antagonists to cardiac dilatation and imperfect systole, if the degree of failure and the anatomical conditions involved permit such tentative tactics; or combine these in certain circumstances with mercurials, neural stimulants, or more powerful vaso-motor agents such as the nitrites. Fortunately, in many instances these measures are soon successful. Not every abdominal case comes to laparotomy, nor does every cardiac case require a bolder method of control. But, on the other hand, many cases unfortunately *do* require such treatment if they are not to be allowed to drift into hopeless failure. The danger *then* lies, as in abdominal cases, in delay, with merely palliative treatment and the Micawber-like expectancy of something beneficial resulting from a timid use of agents and a plaintive hope in the recuperative powers of unaided nature. A large majority of the cases of which I speak are met with in people either young or in the prime of life. The vessels are pliant, the reserve force of the patient is commensurate with his development and age, but the golden bowl is broken and the silver cord is in imminent peril of being loosed unless we can effectively come to the aid of the labouring heart and surcharged venous system. How are we to do this? How is the patient to be prepared for the action of an agent which, held by the physician in a vial, is as powerful for good and for evil as the knife which the surgeon holds in *his* hand? The vascular system of the patient must be relieved of a certain quantity of blood if necessary, varying from four ounces to half a pint, by venesection which, for reasons we shall consider later, is more effective than leeching; his anasarcous limbs must be drained by Southey's tubes or by incision; fluid effusion hampering respiration in the chest or the abdomen must be removed so far as possible, and all this, not with any great expectation of these measures being successful in themselves, although this is not impossible, but to prepare the medical patient, as the surgeon prepares the surgical patient, for the use of the powerful agents which the physician has at his command. These are digitalis or its congeners in action, and of these, I think, we shall all agree that digitalis itself and strophanthus are the most useful, as they are also the most powerful, and that their tinctures, which contain all the active principles of the plant, are the most efficient as they are also the least irritating preparations of the drugs in cases suitable for the method I am about to describe. Small doses then in the majority of cases have previously been tried in vain; so far as we can determine the vessels in the case before us are sufficiently normal, and the heart itself is not tethered by firm extraneous adhesion so far as we can discover, or notably obstructed by aortic aneurysm, or occluded at its main arterial outlet by excessive obstructive disease of the aortic valves. These are important considerations in the use of digitalis, the employment of which in heart disease bears a certain analogy to the beneficial use of ergot in atony or fatigue of the uterus. I need not remind those with the obstetric experience of many of my present audience that the guide in the confident administration of sufficient doses of ergot is the presence or absence of a free uterine and pelvic outlet. So, too, from the bold use of digitalis we expect most benefit when the atonic heart lies behind an unobstructed aortic orifice and normal aorta. The fœtus in the one case and the blood in the other can then be shot out with least risk or distress to the propelling organ. Favourable conditions then being present, so far as we can determine, the drug may be given in ingravescent cardiac failure in 15, 20, 25, or 30 minim doses in the adult, at intervals of four hours, until a definite effect is produced upon the action, force, and capacity of the dilated and failing heart. This may require the continuous administration, in such doses, of the combined tinctures of strophanthus and digitalis, until [illegible] been taken. The patient may [illegible] he course but his labouring [illegible] oothly, and with increased [illegible] experience a relief to which he has been a stranger for weeks. This effect may be permanent or it may be transient. The physician is not always successful any more than the surgeon. But both may have worked for and merited a success which they cannot always command. In laying emphasis on this principle of boldness in the use of the digitalis group in appropriate circumstances I am quite aware that I am not inculcating a new doctrine, for it is as old as Withering who first used digitalis with success in certain dropsies, of the organic cause of which he was ignorant, and it has been taught with no uncertain voice by others, and notably in recent times by the late Dr. George Balfour. But I defy anyone to say that it is not a doctrine which has been preached in large measure to deaf ears and we still find physicians, whether specialists or generalists, employing from week to week doses and methods which are little calculated to affect the action of the heart which underlies the clinical state I have described. One reason for which this bolder method of treating ingravescent cardiac failure has met with less recognition from the profession than it is, in my opinion, certain, sooner or later to secure, is, I think, the want of precision in the instructions given by those who have used it, in the preparation of the patient, and his management during the period of treatment. It must be admitted that this method is more conveniently carried out in hospital than in private practice and for obvious reasons. The family physician, from the multifarious calls made upon his attention, time, and strength, may find it, for geographical and other reasons, difficult to supervise and to carry out all these manœuvres with the care and closeness of observation which they require. But if it be the right course to pursue, and experience has convinced me that it is, in the circumstances I have briefly sketched, is the patient to be accommodated to the convenience of the practitioner or must the latter accommodate himself to the needs of the patient? This question requires no answer. Let the practitioner, therefore, have a trustworthy assistant or send his patient, rich or poor, where the method can be efficiently and as safely as possible put into execution. But, as a matter of fact, it is quite within the power of the practitioner to supervise his case sufficiently if he be provided with good nurses.

In an age of baths and exercises and foreign travel, all of which are very suitable for minor degrees of cardiac failure or after established convalescence from it, I am aware that it will take some time to convince the public, and if I may say so, with all due deference, some sections of the profession also, of the necessity or desirability of such boldness in the treatment of heart disease as I have described. But I believe the days of the expectant physician's influence in this sphere are numbered, be he consultant or general practitioner, and that a few years will find these views generally accepted and acted upon. The task of testing the value of this bolder and as I believe more effectual method, however, and the education of the public to an admission of its necessity, which is commensurate with its gravity, lies largely in the hands of him who comes first in contact with these cases—namely, the general practitioner of medicine, who has already been the successful because convinced missionary of the necessity for boldness in the no more and no less important field of abdominal disease. But it may be asked, Is there not an element of unjustifiable risk in this rapid method of obtaining cardiac control? I answer no, provided such suitable cases as I have indicated be selected for submission to it and the effects of the drug be carefully watched, as is quite possible provided sufficient skilled supervison be exercised. I shall, however, answer the question also by asking another. Has the surgeon alone a prescriptive right to assume responsibility and to take risks in the attempt to save life? It may be contended that the cases are not parallel and that the surgeon operates when operation may not be free from danger to restore diseased parts to a normal condition or to a condition compatible with long life and that he has more control over the means he employs, whereas the physician is dealing with an already diseased organ which cannot be expected to be wholly restored to a normal state and lets loose forces which he cannot control so well. So much may be granted, but the physician's action if successful may restore comparative health, it may be for years or for a period, very beneficial to the patient and those dependent upon him, while the control of his agent merely requires skill and carefulness. The only alternative, moreover, is, in the majority of the cases in which the method is applicable, to stand aside and to watch the patient slowly or suddenly die or to play with remedies in an ineffective and irrational manner and in the fatuous hope that the *vis medicatrix naturæ* may in some inexplicable manner come to the rescue. Such a course, I submit, is neither fair to the patient nor becoming in the educated physician. But it is unnecessary to labour this point further, for the anæsthetist must, I presume, be regarded as a physician rather than a surgeon, and he daily administers an agent at considerable risk and sometimes with a fatal result, which is justified by his attempt to spare the patient pain and to shield him from shock under surgical procedures, at times still more dangerous, though justifiable, than the anæsthetic. The method of obtaining rapid control of the heart in cardiac failure is justified on the same grounds as the action of the surgeon—namely, the attempt to save life, while the risk the physician assumes in this matter is not greater than that assumed by the anæsthetist daily and indeed not so great. But the capable anæsthetist keeps a sharp eye on his patient's condition while submitting him to the drug and the physician who undertakes the rapid control of the failing heart must do so likewise.

The efficient treatment of the *hæmic* factor in cardiac failure takes into consideration the quality, quantity, and distribution of the blood. The influence of occlusion of the coronary vessels has, I think, been over-estimated. As Dr. S. West and Mr. J. Wickham Legg have shown, and as I also demonstrated in my lectures on Cardiac Pain,[3] the very free anastomosis between the right and left vessels secures an adequate blood-supply to the cardiac muscle even when one vessel is practically obliterated. It would be manifestly impossible to enter into a full discussion even of what we know of the quality of the blood in cardiac failure on the present occasion. The important bacteriological aspect of this question is still largely a matter of future knowledge although good work has already begun in this sphere. Nor is it necessary for me to insist on the importance of securing free aeration of the blood in acute cases, and if possible a normal percentage of hæmoglobin in the blood of chronic cases and in debilitated patients. Oxygen gas, so much used to-day, was also employed so long ago as in Hope's day in cyanosed conditions, although Hope probably never witnessed the installation of three or four cylinders of gas at the same time in the same bedroom, as has been suggested, to hiss health into the veins of ailing Crœsus. Like others, I have used Brin's cylinders, but confess that I have never convinced myself that in cardiac cases they had any advantage over an open window, except perhaps in a turgidly cyanotic phase of cardiac failure. *Inflammation of the heart* may be regarded as directly due to defective quality of blood in most cases, but as serum therapy is still largely a question for the future to develop and to apply we must at present content ourselves with treating as efficiently as possible not the cause but the effects of inflammation. The remedy or assuaging agent *par excellence* in this condition is opium. Its efficient use requires its administration in sufficient quantity. The adult probably has frequently sufficient doses administered to him. But the fear of over-action often stays our hand when dealing with children. I desire to state that personal experience has convinced me that children the subjects of carditis can profitably take much larger doses of opium with benefit than is usually supposed, and that either by the mouth or hypodermically.

As regards the regulation of the *quantity* of the blood in cardiac failure one would have supposed that there would now have existed a general consent as to the mechanics if not the utility of blood-letting. But a recent correspondence in the medical press reveals the fact that there are those who question the possibility of temporarily relieving the distension of an over replete right ventricle by this means. Were this scepticism limited to the question of the utility of *leeching* for this purpose I should feel disposed to agree with those who maintain that blood-letting in cardiac failure is of questionable use. But such consent



Scheme of the systemic and pulmonary circulation.

---

[3] THE LANCET, Nov. 1st (p. 1173), 8th (p. 1246), 15th (p. 1306), and 29th (p. 1443), 1902.

would not apply to the efficacy of venesection in this condition. The difference is due, I believe, to the greater *rapidity* with which blood going to the right heart is withdrawn by venesection as compared with leeching. It is a point which might easily be determined by the experimental physiologist if the opinion of the clinician were called in question. But the mechanical possibility may be demonstrated on a simple schema of the circulation which I have been in the habit of employing for the purpose. L H. is a cistern containing water and representing the left heart; S.A. is the systemic arterial circulation; the Y-tube S C represents the systemic capillaries; while S.V. is the systemic venous system and *s v.* a vein capable of representing a venesected vessel *v s.*, and the perforation *l* at its distal end a leech bite. R H. is the right heart to which is attached a manometer M, containing a column of mercury Hg. From R.H. issues the pulmonary artery P.A., passing to the bottle L., capable of being exhausted of air by aspiration and representing the lungs. Water aspirated into it, *p c*, represents the pulmonary capillaries, the fluid in which may find issue by a neck at the bottom of the bottle and be returned by tubing representing the pulmonary veins *p v.* to the left heart. G is a glass U-tube which prevents collapse of the tubing if the lung bottle be placed at a lower level than the heart as it may be with equal effect. If when the apparatus is filled with water and the mercury stands at a certain level the vein *s v.* be left open at its lower end *v.s.* (venesection) the mercury rapidly falls in the manometer. If the end of *s v.* be held, but water be allowed to escape from the small hole *l* (leeching), the fall in the manometer is slow and slight. If with *s.v.* closed and the aspirated bottle in action the continuity of S V. be momentarily interrupted at *cl.* the mercury at once rapidly falls in the manometer just as it does when venesection is represented. If S V. be left uninterrupted the full aspiration of the lung L. has only small effect upon the mercurial manometer. The conclusion I draw from this simple experiment is that venesection is equivalent to interrupted inflow and that both enable the right ventricle and lungs to act more easily than when the former is over-distended, while the slow reduction of the total quantity of blood by leeching effects this purpose in a proportionately small degree. There is, indeed, a certain analogy between the processes for filling and emptying the venous system. Intracellular transfusion may be compared with leeching and intravenous transfusion with venesection. But intracellular transfusion is, on the whole, more potent in accomplishing the object for which it is undertaken than is leeching in that at which it aims to effect. Venesection is a temporary measure calculated *to relieve the over-distended right heart*, just as catheterism relieves an over-distended bladder. The quantity of blood, I need scarcely add, may also be reduced and regulated by a reduction and regulation of the quantity of food and drink and by the posture of the body as regards its accumulation in the *right side of the heart. Graduated feeding* is as important as graduated exercises when the latter are indicated. But this general truth does not impair the value of venesection as a temporary expedient.

By the *mechanical* factor in the action of the heart in this connexion I mean the *valves* of the organ. The influence of these structures when defective on cardiac failure and upon methods of treatment is proportionate to their degree of imperfection, whether the defect be obstructive or permit regurgitation. There are also important differences in the manner in which they manifest their influence according as the defective structure is in the left or the right side of the heart. While all the valves are naturally of prime importance for the due circulation of the blood, the aortic valve is probably the most important mechanical factor in the left and the tricuspid in the right heart. *The brunt of systemic* arterial pressure is spent on the valve at the aortic orifice, while dextro cardiac propulsion through the homologous pulmonary arterial opening is largely aided by the inspiratory action of the lungs. Consequently failure at the aortic valve alone exerts a more important dilative influence on the left ventricle than failure of the pulmonary arterial valve alone does upon the right ventricle, when these conditions are gradually established by disease and are not due to sudden rupture. So much importance did Dr. George Balfour[4] attribute to the influence of incompetency in the aortic cusps that he advised even orthopnœic aortic cases to be placed recumbent, if necessary by the aid of chloroform, and kept so by means of opiates. That the physics of the circulation indicate this position as very advantageous in the circumstances cannot be doubted when it is possible to secure it without adding unduly to the repletion of the right heart and pulmonary circuit. But it must be borne in mind that the orthopnœic position itself is one not only indicative of the need for more air by the lungs but also of the necessity for less blood in those organs. Both these objects are accomplished in a measure by that position of the body. The uprightness of the venous column impedes the rapid entrance of blood into the right heart and utilises the liver reservoir, while the upright thorax permits of fuller respiration. This being so, treatment on the lines already indicated, when dealing with the muscular factor which may render recumbency more gradually attainable, appears in some cases to be preferable to Dr. Balfour's still bolder procedure.

A degree of tricuspid reflux appears to be a normal condition and the anatomical details of that valve seem to be adapted to allow of a certain amount of regurgitation into the systemic veins by a form of safety-valve action. This point has been exhaustively studied by Dr. G. A. Gibson of Edinburgh[5] who is of opinion that physiological and clinical experience support this view. But as the last barrier between the heart and the systemic venous system, the tricuspid valve may be considered as on a par in importance with the first barrier against arterial reflux—namely, the aortic cusps. When in cardiac failure their overthrow is consentaneous the triumph of death over life is all but accomplished. Even then, however, the patient *may* be snatched from the jaws of death by an efficient use of the lancet and digitalis, but a favourable issue cannot be predicted with any assurance. Defects in the right heart alone, or cardiac failure from purely pulmonary causes, such as pneumonia and emphysema, tend to deplete the left heart. The left ventricle of a fatal pneumonia, if the muscle have any native vigour, is found post mortem to be a small and contracted ventricle. It is the left ventricle of asphyxia in which true cardiac failure plays only a secondary part unless the heart be otherwise degenerated or defective. For this reason the digitalis group requires to be used with great caution, if at all, in these circumstances. If these drugs tend to afford a more powerful right ventricular systole, they also lessen the absorptive power of the left ventricle by decreasing its capacity. The bold use of digitalis is, therefore, contra-indicated in theory and prejudical in practice in such cases.

In conclusion, I feel that I should offer some apology for any apparent dogmatism in the manner in which I have treated this important subject and for not having referred more copiously to the work of others. The scope of the subject, the necessity for brevity, and the fact that I have only related what I have also witnessed and drawn conclusions by weighing actual experience must form my excuse for any appearance of having disregarded the published views of others.

Upper Berkeley-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTES ON THE TREATMENT OF TUBERCULOUS MENINGITIS.

By JAMES GILROY, M.B., C.M., L.F.P.S. GLASG.

ON Oct. 10th, 1902, I was called to attend a girl, aged four years. On examination I found that she had widely dilated pupils, a slight elevation of temperature, and a very marked tendency to somnolence, from which condition she woke up at intervals and cried. The mother told me that the child had formerly been bright and cheerful but that of late she had become peevish and fretful. She vomited a good deal and it was evident that the meninges were engorged and the presumption from the family history was strongly in favour of the disease being tuberculous. I attended this case daily, or almost so, until Dec. 22nd following and although for five weeks or more I was prepared for the worst, yet she eventually made an excellent recovery and is at the present moment quite well.

---

[4] Clinical Lectures on Diseases of the Heart, p 103. Third edition.

[5] Diseases of the Heart and Aorta, p. 610.

The method of treatment adopted was one which I have found successful in similar cases and the drug to which I give the major part of the credit was the liquid extract of ergot. I administered it in a four-ounce mixture along with bromide of potassium, iodide of potassium, and syrup of orange, the dose being five minims every two hours. The scalp was also shaved and at first ice was applied at intervals as indicated, after which an ointment of iodoform and vaseline was gently spread on the bare scalp every day.

On Dec. 11th, 1902, I was called to a married woman, aged 50 years, who had somewhat suddenly become delirious. A few days previously she had complained of dyspeptic symptoms. When I saw her she was lifting the coverlet of the bed to throw out some foreign guests which she thought apparently were present in myriads. The symptoms suggested delirium tremens, but knowing the patient well I was convinced that some other explanation must be sought for, and I accordingly came to the conclusion that the case was one of Bell's mania as described by Osler. Here also, just as with the previous patient, a combination of liquid extract of ergot with bromide and iodide of potassium acted wonderfully. The patient made a good recovery in three weeks.

Waterbeck, Dumfriesshire.

NOTE ON THE VALUE OF ICHTHYOL IN TUBERCULOUS GLANDS.

By WALKER OVEREND, M.A., M.D. OXON.,

LATE SENIOR PHYSICIAN TO THE TOTTENHAM HOSPITAL.

ICHTHYOL has been administered with obvious benefit in many instances where suppuration has seemed imminent or has already taken place. I have prescribed it, in the form of two-grain pills, during the initial stages of erysipelas and have been much impressed by its power of inducing resolution of the disease. It has also been recommended in pulmonary phthisis when the cavities have become septic on account of the fact that it favours the process of desiccation. The above considerations led me to give it a trial in the treatment of the enlarged tuberculous glands of childhood. In a child, eight years of age, after an attack of influenza, a large mass which reached the size of a walnut formed on each side of the trapezius and appeared to be on the point of suppuration. There was some difficulty, however, in the exhibition of the drug. Even in solution with a large quantity of glycerine and peppermint the draught is particularly nauseous; in the liquid form ichthyol can hardly be taken. Made into a jelly with gelatine it is not much better and children, as a rule, will neither take pills nor capsules, but they will readily take tablets when made thin and rather smaller than the ordinary size. Tablets of ferrichthyol, each containing one and a half grains of ichthyol combined with iron, probably carbonate or reduced iron, were given three times a day after meals. After four days the glands began to diminish; in a fortnight the enlargements had vanished. The effect of each tablet was shown by a lowering of the temperature. In a boy, five years of age, sent to the seaside with a very large tuberculous lump beneath the jaw, perfect resolution was accomplished after a month's trial of the drug and the question of surgical interference was dismissed after the first fortnight. The treatment was supplemented by an open air life and an appropriate diet in which meat, milk, and eggs, with stimulant, were essentials. The effect, however, is much more marked if the glands have only recently become enlarged. But ichthyol should be given a trial in the chronic tuberculous glands of adults. At times these are liable to suppurate and to discharge for weeks together; ichthyol often checks the secretion and closes the sore.

Clacton-on-Sea.

A CASE OF ACUTE STRANGULATION OF THE INTESTINE BY AN INTRAPERITONEAL BAND.

By HAROLD A. EASTON, M.R.C.S. ENG., L.R.C.P. LOND.

THE patient, a man, aged 61 years, was admitted into the Croydon union infirmary on Dec. 5th, 1902, with abdominal pain (which he referred to the region of the umbilicus), vomiting, and absolute constipation. The onset had been quite sudden on Dec. 1st. The abdomen was moderately distended and tender; palpation revealed nothing in the shape of a tumour mass. There were an inguinal hernia upon the right side and a scrotal hernia upon the left side, both of which, however, were reducible. On his arrival he was in a state of collapse but improved considerably when morphia was administered hypodermically. I diagnosed volvulus and operated on the following morning. Upon opening the peritoneal cavity an offensive smell was perceived. That portion of the small intestine which came into view was deeply congested and hæmorrhagic in places. The hernial orifices were occupied by gut which was easily withdrawn. There was nothing abnormal in the left iliac fossa but the intestine was tied down in the right iliac fossa and on pulling the incision over to the right side the cause of the obstruction was found to be a band about a twelfth of an inch in diameter. This I divided, ligaturing the divided ends. The constricted portion was no more than congested. As the condition of the patient forbade it I made no search for the connexions of the band but proceeded with the suturing of the abdominal incision. I noticed that the mesentery was drawn-looking and evidently cicatricial. There was no recent peritonitis. The peritoneal cavity contained a small amount of a dark, offensive-smelling liquid. The patient died an hour later.

At the necropsy the divided band was identified by means of the ligatures about the cut ends and its attachments were traced to the right internal abdominal ring. Previously to division it formed a loop immediately above and behind the entrance to the inguinal canal, which contained a hernia, and it was surprising that strangulation had been deferred for so many years. The attached ends were about half an inch apart and the total length of the band was one and a half inches. The peritoneum in this situation in particular was cicatricial and just above the attachment of the fatal loop a knuckle of ileum was firmly and closely adherent to it. The patient was evidently the subject of old peritonitis of obscure origin since his appendix was high up and free.

Thornton Heath, Surrey.

THE VERMIFORM APPENDIX ADHERENT IN A HERNIAL SAC AND SIMULATING AN ENCYSTED HYDROCELE OF THE CORD.

By ARTHUR EVANS, M.S. LOND., F.R.C.S. ENG.,

ASSISTANT SURGEON, WESTMINSTER HOSPITAL; SURGEON TO OUT-PATIENTS, SEAMEN'S HOSPITAL, ROYAL ALBERT DOCK.

A BOY, aged three and a half years, was admitted into the Westminster Hospital on April 12th, 1902, with the following history. A swelling was first noticed in the right inguinal region when he was a year old; it was then about the size of a walnut. By the end of a year it had developed into a tubular swelling. The child had worn a truss from the time when the swelling was first noticed. The mother stated that the truss occasionally gave him so much pain that she was obliged to remove, it and this was sometimes the case even when the hernia was, so far as she knew, reduced. Nine months before I saw the boy he had been seen by another surgeon who made the note: "Swelling right inguinal region, probably encysted hydrocele of the cord, with a hernia, reducible." He recommended operation but the surgeon into whose wards the child was admitted did not deem an operation necessary, so the child was fitted with a truss and sent out. When I saw the patient there was a right inguinal hernia which was reducible, but on reduction an elongated swelling, which extended into the inguinal canal, could be felt lying above the testicle and separated from it by an interval; it was hard and rounded and felt like a very tense cyst; it could be reduced almost into the inguinal canal but not quite. It was considered to be a hydrocele of the cord and on account of the pain which the truss occasioned the child I decided to cure the hernia and the cyst of the cord at the same time.

On opening the hernial sac the appendix and the cæcum were found; the appendix was about four inches long, with its apex attached by a fibrous band to the lowest part of the sac. The appendix was amputated close to the cæcum, the gut was returned into the abdomen, and the hernial sac with the adherent appendix was dissected out and removed. Three sutures were put into the abdominal ring, the wound was sewn up and a collodion dressing applied; the stitches were removed on the ninth day. The child left the hospital on the nineteenth day after the operation and has remained quite well up to the present time (1903).

MILL ROAD INFIRMARY, LIVERPOOL.

TWO CASES OF TUBAL GESTATION; RUPTURE; ABDOMINAL SECTION; RECOVERY.

(Under the care of Dr. NATHAN RAW.)

FOR the notes of the cases we are indebted to Dr. E. N. Cunliffe, assistant medical officer.

CASE 1.—The patient was a woman, aged 26 years. Two previous pregnancies had occurred, one seven years before and the other two years. The former pregnancy was followed by some inflammation of the appendages with pain in the iliac regions. The second pregnancy was apparently quite normal. The patient continued to suckle her second child till two or three days before admission. The periods were regular till September, 1903, when sudden cessation occurred. Total amenorrhœa followed without any irregular hæmorrhages. No other signs of pregnancy were noticed and pain was entirely absent. On Nov. 21st the patient was suddenly seized with a violent "cramp-like" pain in the lower part of the abdomen and she vomited. There was also a discharge of blood per vaginam. The pain increased in severity and on the 24th she presented herself for admission to the hospital.

On admission the patient was extremely blanched and collapsed. The pulse was of poor volume, low tension and thready, and could not be counted at the wrist. The heart beats were feeble and averaged 130 per minute. There were excessive pain and tenderness over the lower part of the abdomen which was somewhat distended. On vaginal examination a soft, boggy mass was felt in Douglas's pouch, pushing forwards a slightly enlarged uterus. A diagnosis of ruptured ectopic gestation was made and the advisability of immediate operation was considered. The extreme collapse of the patient and the consideration that the rupture must have happened three days previously led to operation being deferred till next morning. In the interval stimulants were cautiously exhibited and a quarter of a grain of morphine was administered to relieve the obvious anxiety.

Dr. Raw performed the operation. The condition of the patient had somewhat improved, the pulse being palpable at the wrist and averaging 126 beats per minute. Ether was chosen as the anæsthetic and was excellently borne. A median incision about three inches long was employed and on opening the abdomen there was an immediate outrush of a very large quantity of recent blood containing numerous clots. The blood was rapidly evacuated and the uterus and its appendages were explored. The left tube was apparently normal but the right tube was dilated and had evidently been the site of a tubal pregnancy. Its pedicle was defined and secured by double interlocking silk ligatures. The distal portion of the tube was then excised, together with the ovary. The abdominal cavity was irrigated with large quantities of hot normal saline solution. Bleeding had now ceased and the abdominal wound was stitched up in the usual way, a Keith's glass drainage-tube being left in the lower end of the wound. The condition of the patient materially improved during the operation, the pulse-rate falling to 112 beats per minute with improvement of its volume and tension. No fœtus was discovered although careful search was made in the blood clots evacuated. Examination of the diseased tube showed a mass of membranes containing an amniotic sac protruding apparently through the ostium abdominale so that the case was probably one of tubal abortion rather than tubal rupture. The further progress calls for little comment except to remark that the rectal administration of normal saline solution to the amount of a pint five or six times a day was of great service in alleviating a distressing thirst. The Keith's tube was left in for four days and caused a little local suppuration and the production of a sinus that healed with some difficulty. The patient was discharged cured on Jan. 9th.

CASE 2.—The patient was a woman, aged 28 years. She had had two previous pregnancies. The first, 11 years ago, terminated in the delivery at the sixth month of a still born child. The second confinement took place 15 months later, a normal, healthy child being delivered. There was no history of any pelvic trouble and during the following nine years the periods were quite regular. Two months before admission amenorrhœa established itself but this was the only sign of pregnancy observed by the patient. No breast changes were noted and morning sickness was absent. No vaginal hæmorrhages occurred and no pain was felt. On Nov. 26th she was suddenly seized with a violent pain in the lower part of the abdomen more marked on the left side. It was accompanied by vomiting and a discharge of blood per vaginam. The pain became more severe and on the 28th she walked to the receiving room of the hospital and was admitted.

On admission the patient was anæmic but no marked collapse was present though she complained of severe pain. The pulse averaged 72 beats per minute and was of low tension though of fair volume and regular rhythm. On examination there was tenderness over the lower zone of the abdomen on the left side and bimanual examination showed a well-marked, tender swelling of small size present in the left vaginal fornix. The uterus was slightly enlarged, the external os being occluded. In the absence of any signs of a persisting hæmorrhage it was decided to adopt an expectant line of treatment. A one grain opium pill was administered to allay pain and next day her condition was materially improved, little pain being complained of. The pain disappeared entirely in the course of two or three days and abdominal palpation was readily borne and showed no definite swelling though bimanually thickening to the left side of the uterus was still felt. On the night of Dec. 7th without any apparent cause the patient was suddenly seized with a recurrence of severe pain in the left iliac region. She became blanched and collapsed and vomited and the pulse, though never exceeding 70 beats per minute, became thin and thready. It was decided to operate and she was taken to the theatre without delay.

Dr. Raw performed the operation. The same incision and procedures were adopted as in Case 1. The abdomen appeared to contain even more blood than in the preceding case. The left tube was found to be the site of a ruptured ectopic gestation and was removed, together with the ovary, after securely ligaturing the pedicle. Numerous adhesions, evidently formed at the time of the first rupture, were necessarily broken down in the removal of the tube and considerable oozing took place. One or two large vessels were secured and tied and all further bleeding ceased on pressure. Normal saline solution was again used to irrigate freely the lower abdominal cavity and a Keith's tube was inserted in the lower end of the wound. The fœtus was found free in the abdominal cavity. It was apparently about two months old, measuring 2 2 centimetres in length. The limbs were developed and the first rudiments of sex were observable. The Keith's tube was removed after the second day with the result that no sinus formation ensued as in the previous case. A small superficial stitch abscess formed at the upper end of the wound which otherwise healed by first intention. The patient was discharged cured on Jan. 14th.

Remarks by Dr. CUNLIFFE.—There has lately been a revival of interest concerning the symptomatology and treatment of ectopic gestation. The above two cases present symptoms of some interest and illustrate in a striking manner the advantage of early operation. Many authors have laid stress on the fact that ectopic gestations usually follow at a long interval of time a previous pregnancy and frequently there is a history of tubal or tubo-ovarian inflammation. The present two cases bear out these points. In the first case there was a history of previous pelvic trouble and the first pregnancy was succeeded by an interval of five years. Another uterine pregnancy then occurred to be followed after two years by an ectopic gestation; it is [illegible] of this is that in one case the [illegible] by a healthy tube; in the other it was arrested [illegible] d tube. In the second case no history suggestive of inflammatory mischief in the tubes was obtained, but nine years elapsed between the uterine and the ectopic gestations. Sir J. Halliday Croom[1] has recently laid stress on the occurrence of irregular hæmorrhages and pain in these cases, with aggravation of the early signs of pregnancy, such as breast changes and morning sickness. Neither of these patients exhibited any of these symptoms. The successful issue in these two cases shows the importance of abdominal exploration. The second case is particularly instructive as showing that even if hæmorrhage may cease for a time, yet in the absence of radical treatment recurrence may take place and operation have still to be performed, though under less favourable conditions.

The points of interest in the after-treatment were the successful employment of copious rectal injections of normal saline solution to relieve thirst and the importance of not retaining Keith's drainage tube more than two days in the abdomen.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Hour-glass Stomach.

A MEETING of this society was held on Jan. 26th, Mr. ALFRED WILLETT, the President, being in the chair.

Mr. B. G. A. MOYNIHAN read a paper on Hour glass Stomach. He said that by hour-glass stomach was understood that condition in which the stomach was divided into two portions by a constriction at any point between the cardiac and pyloric orifices. In one rare, in fact unique, case under his care the stomach was trilocular. In another there were three points of narrowing, one in the body of the stomach, one at or near the pylorus, and one about one and a half inches beyond the pylorus, in the duodenum. In this case there were four sacs. As a rule the cardiac complement was larger and had thicker walls than the pyloric. It dilated and became hypertrophied by reason of the great obstruction met with at the scarred and narrow isthmus which connected it with the distal portion of the stomach. The forms of hour-glass stomach were many. As a rule the constriction was near the middle of the organ or near the pyloric end. The isthmus might be very much indurated or it might be tubular with very little or no induration but with some thickening. In most instances the greater curvature seemed to be pulled upwards to the lesser, but in one case he had seen the lesser tucked down to the greater. The cause of hour-glass stomach was next dealt with. Mr. Moynihan stated that two forms were usually described—a "congenital" form and an acquired form. An examination of several specimens and an earnest search through the literature had convinced him that there was no proof whatever of the existence of an hour-glass stomach which was due to a congenital deformity. The absence of any observation of hour-glass stomachs in the fœtus or the young child was very striking. When those who had been describing their specimens used the word "congenital" they seemed to do so without thought or hesitation, accepting, it would appear, the mere existence of the deformity as unquestioned evidence of its congenital origin. So far as he was aware there was not a single specimen or an accurate record in existence which could be accepted as evidence of the congenital origin of this disease. The causes of acquired hour-glass stomach were (1) perigastric adhesions, (2) chronic ulcer, and (3) malignant disease. 1. Perigastric adhesions might arise from many causes. Most commonly they were due either to ulcer of the stomach or to gall-stone disease. 2. Chronic ulcer might cause hour-glass stomach in one of two ways. In the first there was a gradual deepening of the ulcer. As the ulcer approached the serous coat of the stomach a few adhesions formed binding the viscus to the anterior abdominal wall, preventing the bursting of the ulcer into the general peritoneal cavity. If the ulcer was on the posterior surface a soldering to the pancreas might result. When the stomach was anchored in its middle, the pouches on each side, but more especially on the cardiac side, showed a tendency to sagging, and this, with the cicatricial contraction taking place in the ulcer, resulted in hour glass form of the stomach. In one of Mr. Moynihan's cases a malignant mass in the anterior wall had formed an extensive adhesion to the body wall. Another important factor in determining the narrowing of the stomach was spasm and recurring attacks of this nature led to hypertrophy of the circular muscular fibres, and this thickening, together with cicatricial contraction, was responsible for the narrowing found in hour-glass stomach. The symptoms and the signs of hour-glass stomach enabled a positive diagnosis to be made in the great majority of cases. First, if the stomach-tube was passed and the stomach was washed out with a known quantity of fluid, the loss of a certain quantity would be observed when the return fluid was measured. This was Wölfler's "first sign." Secondly, if the stomach was washed out until the fluid returned clear, a sudden rush of foul, evil-smelling fluid might occur, or if the stomach was washed clean and the tube withdrawn and passed again in a few minutes several ounces of dirty offensive fluid might escape. The fluid had regurgitated through the connecting channel between the pyloric and cardiac pouches. This was Wölfler's "second sign." If the stomach was palpated and a succussion splash was obtained, the stomach-tube passed, and the stomach apparently emptied, palpation would still elicit a distinct splashing sound. This was due to the fact that only the cardiac pouch was drained; the contents of the pyloric pouch remained undisturbed and caused the splashing sound on palpation. For this phenomenon Jaworski had suggested the appropriate name of "paradoxical dilatation." Von Eiselsberg had observed in one case that on distending the stomach a bulging of the left side of the epigastrium was produced; after a few moments this gradually subsided and concomitantly there were a gradual filling up and bulging of the right side. Von Eiselsberg also called attention to the bubbling, forcing, "sizzling" sound which could be heard when the stethoscope was applied over the stomach after distension with carbon dioxide. If the two halves of a seidlitz powder were separately given and the stomach was normal or dilated, no loud sound was heard anywhere except at the pylorus; if a constriction was present in the stomach a loud, forcible, gushing sound could be easily distinguished at a point two or three inches to the left of the middle line. The abdomen was carefully examined and the stomach resonance was percussed. A seidlitz powder in two halves was then administered. On percussing, after about 20 or 30 seconds, an enormous increase in the resonance of the upper part of the stomach could be found, while the lower part remained unaltered. If the pyloric pouch could be felt or seen to be clearly demarcated the diagnosis was inevitable, for the increase in resonance must be in a distended cardiac segment. If the abdomen was watched for a few minutes the pyloric pouch might sometimes be seen gradually to fill and to become prominent. Schmidt-Monard and Eichhorst had both seen a distinct sulcus between the two pouches inflated with carbon dioxide. Ewald had called attention to two signs which he considered of value in establishing a diagnosis. When the stomach was filled with water and examined by gastro-diaphany the transillumination was seen only in the cardiac pouch; the pyloric pouch remained dark. The deglutable indiarubber bag of Turck and Hemmeter was passed and distended. The bulging caused thereby was limited to the cardiac pouch which lay to the left of the middle line. The two aids to diagnosis of greatest value were, it will be seen, the washing out of the stomach and its inflation with gas by the administration of a seidlitz powder in two portions. The fluid used for the washing must be carefully measured before use; the tube was then passed and the stomach emptied, the contents were set aside in a separate dish, and the washing was commenced. All the fluid now returning was collected in a separate vessel and carefully measured. The two signs of Ewald were of little importance; a correct diagnosis could always be made without them. With regard to treatment, Mr. Moynihan said that in many cases of hour-glass stomach there was a narrowing not only in the body of the stomach but also at the pylorus. This illustrated the undoubted fact that gastric ulcer was often multiple. The result, so far as the treatment of the condition was concerned, was that in many of the cases no single operation would suffice to fulfil all the requirements. If gastro-enterostomy was performed from the cardiac pouch the pyloric pouch remained undrained. Symptoms of stasis were then observed, as in a case recorded by Terrier, and a second operation was necessary. An anastomosis from the second pouch was obviously futile. A gastroplasty which relieved the obstruction in the body of the stomach did not deal with the pyloric narrowing. In many cases it was necessary to perform a double operation, gastro enterostomy from both pouches, gastroplasty combined with gastro enterostomy from the pyloric pouch, gastro-gastrostomy with gastro-enterostomy, or gastroplasty and pyloroplasty.

---

[1] Practitioner, November, 1903.

Mr. STEPHEN PAGET asked if any sort of bobbin had been used in performing the gastro-gastrostomies.

The PRESIDENT, after congratulating Mr. Moynihan on his paper, said that the observations on the so-called congenital hour glass stomach were of special interest and it seemed probable that it did not exist since no authentic instance of such a condition could be found. He thought that a good many instances of hour-glass stomach must be overlooked. He referred to the fact that the disease was more common in women than in men, 11 of the cases recorded being in women and seven in men. He asked if there was anything in the mode of living, occupation, or diet which gave rise to the greater frequency of hour glass stomach in the north of England than in London.

Dr. G. B. FERGUSON (Cheltenham) asked whether antiseptics had been used or whether the operation had been done with only aseptic precautions.

Mr. H. J. PATERSON referred to the somewhat high mortality in the series of cases. He related a case in which perforation of an ulcer had taken place near the pylorus in which an hour-glass stomach was found to be present and suggested that had an operation been performed on the hour-glass stomach at an earlier date the pyloric ulcer would have been relieved.

Mr. MOYNIHAN, in reply, said that he could not account for the greater prevalence of the hour-glass stomach in the north of England. The taking of large quantities of tea and dry bread was the only marked difference of diet. He had noticed that duodenal ulcers nearly always occurred in those who drank beer to excess. He thought the mortality was higher than it ought to be, but that was probably in part due to the ill health of the patient produced by the prolonged disturbance of nutrition while the contraction of the stomach was taking place. The accumulation of fluid in the distal portion of the stomach which could not be washed out might also account for the increased risk of the operation. He only used a needle and thread in making his anastomoses and never used any antiseptic within the abdomen. He was of opinion that hour-glass stomach was much more common than was generally believed.

CLINICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Jan. 22nd, Dr. FREDERICK TAYLOR, the President, being in the chair.

Dr. F. PARKES WEBER showed two cases of Diffuse Lipomatosis. The first case was that of a single woman, aged 34 years, who presented typical diffuse lipomata below the lower jaw, on the upper arms, and on each side of the front of the thorax. She had always enjoyed good health. The condition had been noticed for about two years and was unassociated with pain. She had been treated by thyroid tabloids. The second case was that of a man, aged 52 years, who was formerly a carman. There were huge lipomatous masses affecting the neck, arms, and pubic regions. They had first appeared in 1868, after an injury. There had been slight general wasting, in connexion with which it was suggested that there might be some cirrhotic change in the liver. The

o difference between

ged ten years, with in August, 1903, he

a year and to have had pain and swelling in the left side. The liver was then much enlarged and reached below the umbilicus. It was firm and not tender. One large and several smaller swellings were felt on the surface of the right lobe near the costal margin, which were hard and yielded no fluctuation. The lymphatic glands in the neck were enlarged. There were double dacryocystitis, conjunctivitis, and interstitial keratitis more marked in the left eye. There were no changes in the fundi. The teeth were badly formed but were not characteristic of congenital syphilis. He had taken iodide of potassium almost continuously and the liver had diminished in size. It was thought that the tumour was probably of a gummatous nature but the diagnosis of hydatid had also been advanced. No blood changes had been observed.—Dr. G. A. SUTHERLAND thought that the hardness of the mass as well as the presence of old keratitis strongly suggested gummata. He suggested that mercury should be employed in the treatment.—The PRESIDENT asked if there had been pyrexia at any time and referred to a similar case recorded by the late Dr. J. S. Bristowe in the transactions of the society.

Mr. W. H. B. BROOK (Lincoln) showed a case of Total Paraplegia due to caries of the mid-dorsal vertebræ, for which the operation of costo-transversectomy had been performed with complete recovery. The patient was a youth, aged 18 years, the notes of whose case had been read before the society in March, 1903. The fact that the patient had undertaken a railway journey of over 100 miles was in itself sufficient evidence of the completeness of his recovery.—Mr. LAWRIE H. MCGAVIN considered that the thanks of the society were due to Mr. Brook for bringing the case before its notice and congratulated him upon such a successful issue.

Mr. J. R. LUNN showed: 1. A case of Chronic Periostitis (syphilitic) in a man, aged 28 years, affecting the lower ends of both femora. A skiagram was shown to illustrate the condition. 2 A case of Ununited Fracture of the Radius and the Ulna in a man, aged 74 years, which had existed for a period of 38 years. The accident was a compound one and when first seen he was advised amputation but he refused. 3. A boy, aged 13 years, with symmetrical swellings on the lower jaw. He was also the subject of congenital syphilis.

Mr. WALTER G. SPENCER exhibited a boy, aged ten years, with Bilateral Enlargement of the Testicles. Both testes were swollen to about adult size and were firmly elastic but not tender; the right was enlarged and the left was less so. A sinus existed over the front of each testis which had ceased to discharge pus and appeared to be healing. The patient did not present any further signs of past or present disease. An indefinite family history suggested both tubercle and syphilis. He had been under observation for three weeks and was treated with mercury internally and locally with a little iodide.—Mr. A. A. BOWLBY and Mr. RAYMOND JOHNSON agreed that the case was one of tubercle.

Dr. FREDERICK E. BATTEN showed a girl, aged five years, the subject of Complete Ophthalmoplegia Externa with Blindness of acute onset. 13 weeks before admission to hospital the child had whooping-cough, from which she recovered in about six weeks. One week before admission the mother noticed that the child could not see. At the same time it was noticed that the pupils were very large and she could not move the eyeballs. There was no loss of consciousness and there were no convulsions. On admission there was no ptosis but complete ophthalmoplegia was present, with a slight divergent strabismus. The pupils were widely dilated and did not react to light. There was complete blindness. There was slight optic neuritis, which was more marked in the right eye than in the left. There was no weakness of the muscles of the face, tongue, palate, or limbs. All the deep reflexes were abolished. 14 days after admission the movements of the eyes had become normal, the pupils were no longer so dilated, and the optic neuritis was much less. There was no return of vision and the knee jerks still remained absent. It was suggested that the case was one of polio-encephalitis inferior affecting the oculo-motor nuclei and the lower visual centres.

Mr. MCGAVIN showed a married woman with Complete Absence of the Phalanges of the Left Hand. The patient, who was the sole member of her family affected by any bodily deformity, was healthy in other respects. The skiagram showed that the whole of the phalanges had been suppressed.

Mr. JOHNSON showed a man, aged 28 years, with a Translucent Cystic Swelling of the Root of the Nose. The condition was first noticed about three years ago. No cause could be assigned and it had slowly increased without pain. The cyst gave a well-marked sense of fluctuation and its tension appeared to be quite constant. It was possible that it was of parasitic origin. Its extreme translucency rather pointed to the presence of a dermoid.

Mr. JOHNSON also showed a man, aged 47 years, the subject of Multiple Aneurysms, in whom an aneurysm of the right brachial artery was removed by operation in July, was to take out the appendix at the very first—namely, on the first or second day, introducing one or two fingers through a small incision. In this way there was no risk of ventral hernia. If, however, the case were only seen on the third day it was better to wait for the interval. If suppuration had taken place a much larger opening was necessary in the abdominal wall. American surgeons hardly ever had a case of either suppurating or burst appendicitis because they invariably operated early. He thought that the leucocyte count was of the greatest value.

Mr. F. M. Caird said that he regarded cases of acute appendicitis as beginning with a rapid onset and terminating in resolution, operation, or death within 10 or 14 days. In fulminant cases the gravity of the situation was usually at once recognised and operation followed immediately. But when the onset was less acute he believed it was justifiable to temporise. He generally applied an ice-bag, washed out the rectum, and waited for a day or two. If when under observation the patient did not improve, or if he became worse, or if after a temporary lull symptoms again—within ten days—became exacerbated, operation was indicated. Under this treatment many cases got well and surgical interference could be carried out during a quiet interval. Others, again, derived benefit from the limiting peritonitis established during this short probationary period. During the last three years 22 cases of acute peritonitis had been subjected to operation in the wards under his care Two died. They were usually admitted in the third or seventh day of the attack The two fatal cases seemed hopeless from the beginning but two apparently equally so had recovered.

Dr. J. O. Affleck said that acute appendicitis was easily confounded with typhoid fever. There was great risk in giving patients purgatives and enemata; he had seen two cases in which an appendicular abscess was ruptured by an enema. As regarded treatment he had seen great benefit from the application of ice bags to the part—in fact, they seemed to remove the inflammation entirely and he had known of such cases not having a return of the symptoms during the next 20 years. His rule was that after a second of two well-marked attacks occurring within a year the operation ought to be performed after the end of the second attack.

Dr. W. Haldane (Bridge of Allan), Dr. T. M. Burn-Murdoch, Dr. James Ritchie, Mr. H J. Stiles, Mr. C. W. MacGillivray, and Dr. G. Lovell Gulland also took part in the discussion.

Aberdeen University Medical Society.—A meeting of this society was held on Jan. 15th.—Mr. P. B. Roth read a paper on the Treatment of Scoliosis. He first discussed the etiology of the condition, pointing out that it occurred in girls and boys in the proportion of 6 to 1 and between the ages of five and 17 years as a rule. Scoliosis might be either osseous or postural. In osseous scoliosis there was bone disease and the condition was to that extent incurable. In postural scoliosis the curve in about one-half of the cases was a reversed C in the dorsal region, the position assumed when writing with one arm on the table. One-third of the cases exhibited a reversed S curve, the upper concavity facing the left, and the lower one facing the right. The curves were occasionally reversed in these two subdivisions. Before describing the rational treatment Mr. Roth discussed the objections to such apparatus as those of Sayre, Noble Smith, Howard Marsh, and Adams. Shoulder straps, he said, caused sores in front and also an abnormal development of the pectoral muscles, while the muscles attaching the scapula to the spine became wasted. The result was that when the straps were removed the forward stooping was increased. Shoulder straps were useful only in dress to remind the patient that she was expected to brace back her shoulders; they should be made, however, so that they would break on too much pressure being applied. In addition to curvature the other symptoms of scoliosis were stooping at the shoulders and forward projection of the head, a flattened anterior thorax, and a bulging abdomen. It was essential to have the clothing removed in order to obtain a sufficient view of the spine and it was wise to take the position of the spine (1) with regard to the middle of lines extending between the inferior angles of the scapulæ (the shoulders being braced back and any inequality in the length of the two legs corrected by placing a block under the foot of the shorter leg) and (2) between the mid points of lines extending from the subcostal plane to the top of the iliac crests respectively. The patient should then be induced to assume the "best position"—i.e., one which made the spine most nearly approach normal. All subsequent treatment aimed at keeping this position during exercise of all sorts. Exercise was strongly advocated such as breathing movements when lying flat on the back or face in the "best position." This, combined with good food and plenty of fresh air, resulted in the development of those muscles which normally kept the spine in position. The muscular sense was markedly absent in the wasted muscles, as was seen by the grotesque attitude assumed by many patients when asked to put themselves in what they considered the normal position.—Mr. F. L. Keith read a paper on Eclampsia and Status Epilepticus.——At a meeting held on Jan. 22nd, Mr. James Clark presiding, Dr. George Stoddart read a paper on Opportunities of Study in Foreign Schools. Among the various subjects discussed reference was made to the treatment of syphilis by from 12 to 16 hypodermic injections of perchloride of mercury spread over a period of six weeks and to the use of alcohol for disinfection of the hands and for uterine douches. The hands should be scrubbed for five minutes with soap and water and then steeped in alcohol of 60 per cent. strength for other three to five minutes. This method gave better results bacteriologically than other methods in ordinary use.—Mr. Fife Slater read a paper on the Dieting of Infants. He said that the mother ought, if at all possible, to suckle her infant for the first six or nine months and the periods of feeding should be regular: every two hours during the day and every four hours during the night for the first month, every two and a half hours during the day and every four hours during the night for the second month, and so on. "Humanised" milk was the best to use where the mother could not give milk. If it was necessary to change from breast to cow's milk the change should be gradually effected, using whey or peptonised milk before beginning with cow's milk, which ought to be boiled before using. Bread jelly was preferable to artificial foods, but where it was found necessary to use artificial foods they were to be given only as subsidiary to milk diet and not as a substitute for it. Prolonged use of peptonised or sterilised milk was a frequent cause of scurvy and rickets.

Laryngological Society of London.—A meeting of this society was held on Jan. 15th, Dr. P. McBride, the President, being in the chair.—Dr. W. H Kelson showed (1) a case of Deformity of the Fauces in a Woman; and (2) a case of Epithelioma in the Cricoid Plate Region in a woman, aged 30 years.—Dr. A. Logan Turner showed a case of Affection of the Palate and Larynx in a man. The patient suffered from œdema and infiltration of the uvula, the left half of the soft palate, and the left lateral wall of the pharynx. There was infiltration of the epiglottis and both arytenoid regions Dr. Turner considered the condition analogous to certain cases which Sir Felix Semon had shown at the previous meeting.—The case was discussed by the President, Sir Felix Semon, and Dr. J. Dundas Grant.—Dr. Atwood Thorne showed a case of Malignant Disease of the Nose in a man, aged 70 years.—Mr. H. B. Robinson showed: (1) a case of Syphilitic Necrosis of the Sphenoid Bone; (2) a case of Left Abductor Paralysis in a male, aged 31 years; and (3) a case of Syphilis of the Posterior Part of the Tongue and Posterior Pharyngeal Wall.—Dr. L H Pegler showed a case of Crumpled Septum in which he had excised the hard structures four years ago and in which the intact muco-perichondrium remained unstiffened.—Mr. P. R. W. de Santi showed: (1) a case of Laryngeal Vertigo; (2) a man with Tertiary Syphilis of the Larynx causing stenosis, on whom thyrotomy had been performed four years ago with satisfactory results.—Dr. StClair Thomson showed: (1) a case of Complete Paralysis of the Left Vocal Cord in a woman, aged 36 years; and (2) cases of Bleeding Polypus of the Septum.—Mr. H. T. Butlin showed a specimen of Epithelioma of the Cricoid Plate and of the Œsophagus removed by operation The patient was a man, 44 years of age, with a large smooth red tumour at the back of the larynx almost confined to the left side and involving the whole of the ary-epiglottic fold but not encroaching to any extent on the interior of the larynx There was a very large mass of glands on the left side of the neck so intimately associated with the sterno mastoid that their removal could only be carried out by removing almost the whole of the muscle. The disease had started ten months previously as a curious catch in speaking. For four months there was a difficulty in swallowing and when first seen by Mr. Butlin the patient could only swallow with pain and the voice had just become husky. The age and immense strength of the patient and the fact of Professor Gluck's successful operations for what would have appeared to be hopeless conditions of malignant disease of the throat and neck induced him to put the matter before the patient who decided in favour of operation. An extremely extensive operation had to be performed, necessitating removal of the whole internal jugular vein, the glands of the neck, and the whole of the sterno-mastoid muscle on that side. The patient made an excellent recovery but within two months the disease had recurred. He had operated on another case of the same sort but within a week the patient died suddenly from profuse hæmorrhage, probably from the carotid. The case was discussed by the President, Sir Felix Semon, and Dr. P. Watson Williams.—Mr. F. C. Shrubsall (for Dr. Percy Kidd) showed a patient suffering from a Tuberculous Outgrowth from the Anterior End of the Left Vocal Cord.—Dr. Dundas Grant showed: (1) A case of Sessile Fibromata at the anterior extremity of the left vocal cord partially removed by means of forceps and completely extirpated by the galvano cautery; (2) a case of Atrophy and Collapse of the Alæ Nasi treated by means of a Subcutaneous Injection of Paraffin; and (3) Photographs of a case of Flat and Sunken Nose treated by Injections of paraffin. A note of warning was sounded by some speakers as to the dangers that might accrue after the injection of Paraffin.—Mr. Hunter F. Tod showed: (1) A case of Soft Fibroma of the Left Vocal Cord in a woman, aged 31 years; and (2) a case of Sarcoma of the Post nasal Space probably involving the Ethmoidal Region with Enlargement of the Cervical Glands on the Right Side in a man, aged 51 years.—The general expression of opinion was that operation was impracticable.—Dr. Williams showed a man, 42 years of age, with an Intralaryngeal New Growth.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 14th, Dr. Peyton Beale being in the chair.—A discussion on Recent Methods of inducing Anæsthesia was opened by Dr. J. F. Silk who referred to the three stages in the use of anæsthetics, beginning with the elementary stage which lasted until 1890, when the patient dreaded the anæsthetist more than the surgeon; the second stage, during which anæsthetists were divided into the two rival camps of chloroform and ether; and the present stage, when they had recognised definitely that these were not the only anæsthetics and that the true art of the anæsthetist did not lie in pinning his faith to any one anæsthetic but in adapting it to the particular patient. More than this, he could with advantage change the anæsthetic to [illegible] ie same operation. [illegible] modern methods [illegible] as and oxygen he [illegible] very highly of the [illegible] face-piece, especially in the case of young children. Gas and air had the disadvantage that so much gas was used, but Dr. Silk recommended the combination for plethoric patients. In the use of ether he referred to Dr. Probyn Williams's improvement of the small Clover inhaler by increasing the air way and showed the inhaler thus modified. For the administration of chloroform the Junker apparatus with glass inhaler was recommended, although Dr. Silk said that he himself always used a simple drop-bottle and an ordinary mask. He used less and less chloroform; when he could not give ether he fell back on a mixture of one part of chloroform and two parts of ether with which he was very pleased. He then passed on to the newer forms of anæsthetics having chloride of ethyl as their basis. As regarded methods of administration Dr. Silk did not believe any new instrument to be necessary. He used chloride of ethyl as a preliminary to other anæsthetics, as a substitute for gas, and for adenoids (alone), but not for dental cases because the period of anæsthesia could not well be continued should this be necessary. The methods of administration were demonstrated. The great advantages of chloride of ethyl were that it was very rapid, not unpleasant, produced no asphyxia, and needed no big apparatus for its use.—Mr. H. E. G. Boyle, resident anæsthetist at St. Bartholomew's Hospital, deprecated all forms of complicated apparatus as these were incumbrances rather than helps to all except very skilled anæsthetists. A mixture of chloroform and ether he considered very useful, especially in cases that were doing badly with either when given alone. Mr. Boyle then referred to somnoform which he had administered between 600 and 700 times. It was an exceedingly useful anæsthetic but it needed familiarity in order to get good results. The use of 2 5 to 3 cubic centimetres, instead of larger doses, was recommended, being given in a closed bag with a face-piece; in this way from 35 to 40 minutes' quiet anæsthesia was obtained. The time to begin operating was when the conjunctival reflex was lost and the breathing was slightly stertorous. The great thing to avoid was admixture with air; if this occurred there was often vomiting, not unless.—Dr. H. H. Rubra, anæsthetist to the Great Northern Central Hospital, concurred with most of Mr. Boyle's remarks concerning somnoform. He had found it very useful in cases where gas could not be taken He also considered it a better anæsthetic than ethyl chloride, giving less spasm and more perfect analgesia. It had the advantage of not being unpleasant.—Several other members took part in the discussion.

MEDICAL SOCIETY OF LONDON.—A meeting of this society was held on Jan. 25th, Dr. F. de Havilland Hall, the President, being in the chair.—Dr. M. Handfield-Jones opened a discussion on Pelvic Lesions in Relation to Abdominal Diagnosis. The subject, he remarked, was beset with difficulties because the connexion between uterine disease and abdominal inflammations was not always clear. Cases were referred to in which severe nausea and vomiting were dependent on metritis and disappeared on the cure of the latter. Three cases were then narrated in which perforating gastric ulcer had been diagnosed but in which the symptoms really depended on hæmorrhage from rupture of a tubal gestation. The menstrual history in such cases was of little value, nor did pelvic examination lend much aid; the pain might be very diffuse and the effect on the temperature and pulse might be the same in both conditions. Exploratory laparotomy was the only proper course. Cases were next mentioned to illustrate the difficulty of diagnosis of abdominal inflammations and other conditions from those depending on dermoid cyst of the ovary, suppurating cysts of the ovary, and fibro-myoma of the uterus. The pelvic organs should always be examined in suspected abdominal disease. Cases illustrating the part played by pelvic adhesions in producing abdominal symptoms were narrated. Constipation and nausea might be due to adhesions or to bands which might be very easily overlooked, and a case was mentioned which had been operated on by different highly skilled surgeons on six occasions without obtaining relief.—Mr. Alban H. G Doran dwelt on the necessity of following up the after-history of operation cases because reported recoveries were not always real recoveries. He referred to a case of severe dysmenorrhœa in which it was proposed to remove the ovaries but the symptoms were relieved by the patient wearing spectacles suitable for the correction of her hypermetropia.—Dr. Heywood Smith, referring to the diagnosis between ruptured tubal pregnancy and perforated gastric ulcer, remarked that the mammary symptoms were very valuable.—Dr. J. Vincent Bell (Rochester) narrated a case of parovarian cyst which resembled a tumour of abdominal origin.—Mr. Edmund Owen remarked on the value of exploratory operations and said that it was a very remarkable fact that patients recovered after mere opening of the abdomen. He referred to the value of a discharge of blackish blood from the vagina as a diagnostic feature of tubal pregnancy.—The President mentioned the case of a girl aged 12 years whose symptoms suggested appendicitis but were found to be due to a strangulated ovarian cyst.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—The annual meeting of this society was held at the Owens College, Manchester, on Jan. 15th.—Dr. W. J. Sinclair (Manchester) was unanimously elected president of the society for 1904. At the conclusion of the annual business Dr. A. Stookes (Liverpool) read notes of a case of Eclampsia with fatal result.—A discussion followed in which the President, Dr. H. Briggs, Dr. Martin, Dr. Croft, Dr. Nesfield, and Dr. J. E Garner took part.—Dr. A. Donald (Manchester) read a paper on Chronic Endometritis and Chronic Metritis in Virgins. He dealt with affections of the endometrium and mesometrium occurring apart from the usual infective causes (sepsis, gonorrhœa, &c). The paper was based on a series of 40 cases which had been carefully observed. Attention was specially directed to one group of cases which were characterised by the association of these three conditions: (1) small or infantile cervix; (2) acute flexion, forwards or backwards; and (3) enlargement of the uterine body. The symptoms in these cases were in the order of frequency: (1) pain or dragging sensation in one or both iliac regions, or pain generally in the lower zone of the abdomen (in 36 out of 40 cases); (2) dysmenorrhœa (in 33 out of 40 cases); (3) leucorrhœa (in 31 out of 40 cases); (4) menorrhagia or metrorrhagia (in 16 out of 40 cases); and (5) remote or nervous symptoms. In a large proportion of the cases the uterine mucosa was much thickened. The uterine cavity showed an increase in length of from a quarter of an inch to one and three-quarter inches and the mesometrium was sometimes considerably thickened. Microscopic examination of the mucous membrane removed showed great increase in glands or in interglandular stroma or both. Remarks were made as to the etiology and treatment of the condition.—The paper was discussed by Dr. D. Lloyd Roberts, Dr. Arnold W. W. Lea, Dr. W. E. Fothergill, Dr. Stookes, Dr. Richardson, and the President.—Dr. Donald replied.

Aberdeen Medico-Chirurgical Society.—A meeting of this society was held on Jan. 14th, Dr. J. Theodore Cash, the President, being in the chair.—The following clinical cases were shown: Dr. H. M. W. Gray (for Dr. J. Mackenzie Booth): A case of Double Undescended Testes in which reposition had been effected by Annandale's method.—Dr. J. F. Christie: A woman suffering from a Chronic Diffuse Infiltration of the Skin of the whole Body with Formation of "Tubercles" on the Face. The case had been diagnosed two years before at the Dermatological Society of London as lymphodermia perniciosa.—Dr. G. M. Edmond: (1) A case of Disseminated Sclerosis; (2) a case of Functional Paraplegia; and (3) a case probably of Cerebellar Tumour.—Dr. Gray: A case of Tendon Transplantation for Musculo-spiral Paralysis. The flexor carpi ulnaris tendon was cut, brought through the interosseous membrane, and attached to the extensor tendons. Marked improvement in extension of fingers and in supination followed.—Dr. R. G. McKerron: A case of Leucocythæmia of the spleno-medullary type in a boy, aged 12 years. 48 per cent. of myelocytes were present.—Dr. J. Marnoch: (1) A case in which Suprapubic Prostatectomy had been performed with complete success for prostatic hypertrophy; (2) a case of Non-malignant Pyloric Stenosis with a considerable tumour at the pyloric region in which posterior gastroenterostomy had given complete relief to the symptoms; (3) a case of Perforated Gastric Ulcer in which operation had been performed within five hours of the perforation; and (4) a child, aged three years, operated on ten months before for Tuberculous Peritonitis; the abdomen had been simply opened, not drained. The child now appeared quite well.—Dr. G. Rose: (1) Two cases after Disarticulation at the Hip-joint by McBurney's Method; and (2) a case after Excision of a Large Spina Bifida Tumour at the age of one month.

Clinical Society of Manchester.—The monthly meeting of this society was held on Jan. 19th, Dr. W. Milligan, the President, being in the chair. Dr. Eugene S. Yonge showed new Self-retaining Basins for Nasal and Aural Work; also a new apparatus for demonstrating the Laryngeal Image and Intralaryngeal Manipulations. By this apparatus (invented by Professor Meyer of Berlin) a beautiful image of the larynx could be obtained by five observers at a time, including, of course, the examiner. Also, intralaryngeal manipulations were as clearly observed by the bystanders as by the operator. It appeared, so far as Dr. Yonge knew, to be the best apparatus extant for the purposes indicated.—Dr. G. H. Lancashire read a paper on Some Specific and Tuberculous Affections of the Face. The various syphilitic manifestations commonly met with in this region were discussed and clinical features were described which served to differentiate them from other skin diseases. Tertiary syphilitic disease was dealt with at greater length and especial mention was made of those cases simulating lupus vulgaris and *vice versâ*. In all doubtful cases the adoption of a preliminary antisyphilitic treatment was urged and the danger of immediate surgical procedure in these cases was emphasised. Finally, attention was drawn to that small group of cases in which both syphilis and lupus were combined in the same lesions. Photographs, plates, and cases were shown illustrating the paper.

Royal Medical Society of Edinburgh.—A meeting of this society was held on Jan. 15th, Dr. O. J. Shaw being in the chair.—Dr. J. Murdoch Brown read a dissertation on Cyanosis.—Dr. A. C. Geddes read notes of the case of a boy admitted to hospital suffering from a peculiar linear burn, of the second degree, on the right side of the thorax. The burn was treated as usual with picric acid. During the night following admission the patient passed into a state of extreme collapse with a pulse of over 200 and marked Cheyne-Stokes respiration. The interest of the case lay in the fact that while in this condition a peculiar cyclical change was noticed in the boy's colour. Thus, beginning with deadly pallor, his face would gradually assume a more healthy hue, from which it passed on to flushing and then deep cyanosis, and back again to pallor. This cycle took about four minutes to pass through, while the Cheyne-Stokes respiratory cycle only occupied from 60 to 80 seconds. So far as was known this condition had not been previously described.—Dr. G. J. Farie read notes on a case of Submucous Fibroid of the Cervix Uteri. The tumour caused profuse hæmorrhage and was removed by panhysterectomy. In the specimen which Dr. Farie showed, there was a remarkable enlargement of the cervix by the tumour—the uterus, which was of normal size, being only about one-quarter the length of the cervix.

Plaistow and Canning Town Medical Society.—The fifth annual meeting of this society was held on Jan. 21st, Mr. Percy Rose being in the chair. The annual report was read and passed.—Mr. J. Jordan Harvey showed specimens of (1) Placenta Circumvallata; and (2) Placenta Succenturiata.—Dr. E. Hay exhibited a case of Dilatation of the Stomach.—The following gentlemen were elected office bearers for the year:—President: Dr. W. C Taylor. Vice-President: Mr. Harvey. Honorary treasurer: Dr. W. M. D. Gallie. Honorary secretaries: Dr. Hay and Dr. E. P. McLoughlin.—Mr. Rose opened a discussion on the Responsibilities that might be thrown on Medical Men under the Midwives Act and the Absence of any Provision for securing Payment. He was of opinion that the payment of those fees should be undertaken by the local supervising authority and concluded by submitting a scale of fees.—A discussion ensued in which the majority of those present joined and generally agreed with the scheme proposed. It was decided to approach the local supervising authority on the matter.

Pathological Society of Manchester.—A meeting of this society was held on Jan. 20th, Dr. E S Reynolds, the President, being in the chair.—Mr. J. Collier exhibited specimens of (1) Chondro-Sarcoma of the Os Calcis and (2) Pancreatic Cysts.—Dr. E. S Yonge made a communication on the Recurrence of Nasal Polypi, with special reference to the theory of bone disease.—Mr. Smith mentioned a case of Non-traumatic Rupture of the Bladder and showed the specimen.—Mr. John B. Wolstenholme exhibited the Cervical Vertebræ of an old male horse affected with osteomalacia associated with periostitis, in which spontaneous fracture of a process of the sixth and of the seventh had occurred. He also exhibited mounted specimens of the Sarcoptes Scabiei, variety Equinus, together with a section of skin showing galleries with acari, &c., therein.

Æsculapian Society.—A meeting of this society was held on Jan. 22nd, Dr. Leslie Durno, the President, being in the chair.—Mr. W. Campbell M'Donnell showed a man, aged 34 years, at whose Cardiac Apex was heard a Systolic Noise audible only during inspiration.—Dr Alexander Morison read a paper on the Efficient Treatment of Cardiac Failure, which will be found in full at p. 291 of our present issue. A general discussion followed to which Dr. Morison replied.

Society for Relief of Widows and Orphans of Medical Men.—A quarterly court of the directors of this society was held on Jan. 13th, Mr. Christopher Heath, the President, being in the chair. Three new members were elected and the death of a member was reported There were no fresh applications for grants. It was resolved to distribute £1513 among the 53 widows, 15 orphans, and four recipients from the Copeland Fund now in receipt of grants. A sum of £586 had been given at Christmas as a present, £10 each to 53 widows, £3 each to 12 orphans, and £5 each to the four orphans on the Copeland Fund. The expenses of the quarter were £77 12*s.* 6*d.*

Reviews and Notices of Books.

A Manual of Medicine. Edited by W. H. ALLCHIN, M.D., F.R.C.P. Lond., F.R.S. Edin., Senior Physician and Lecturer on Clinical Medicine, Westminster Hospital, Examiner in Medicine, Naval Medical Service. Vol. V., Diseases of the Abdominal Organs London: Macmillan and Co., Limited. 1903. Pp. 687. Price 10*s*.

THIS volume is a comprehensive one and contains articles on diseases of the digestive system and of the liver; on diseases of the peritoneum and of the vessels of the abdomen; on diseases of the kidneys; and on diseases of the ductless glands.

The digestive organs are first discussed. The general anatomy and physiology of these organs are admirably described by Dr. Allchin and then follows a well-written disquisition on Food and Diet by Dr. R. Hutchison. His remarks on the digestibility and absorbability of foods are worthy of close attention. He shows that the physical form of a food has more influence upon the ease with which it is digested than any other consideration. Fineness of division greatly facilitates solution in the stomach. On the other hand, all tough and hard articles of diet are dissolved with difficulty, while the presence of much fat in the interstices of a food militates against rapid disintegration by preventing the ready ingress of gastric juice. The quantity of any article eaten has less influence on its digestibility than its consistence. Doubling the quantity, for instance, does not mean doubling the time required for digestion but only prolonging it by about one half. Dr. Hutchison further draws attention to the influence which certain accompaniments of meals have upon the rate of digestion. He states that water is almost devoid of any influence unless the amount taken is excessive; hot water even accelerates digestion. Tea and coffee delay it, both in the mouth and the stomach, but alcoholic drinks have "astonishingly little effect" and, so far as the stomach at least is concerned, may even accelerate the process by promoting a flow of gastric juice.

Equally interesting are the observations of Dr. W. S. Lazarus-Barlow on the Bacteria of the Alimentary Tract. He points out that the experiments of Schottelius tend to show that the enzymes are incapable of exerting their full power until aided by the bacteria which appear normally in the excreta in thirty-six hours after birth; therefore it would seem that the organisms found in the alimentary canal are of service to the economy of their host. Dr. Lazarus-Barlow considers that it is certain that the bacteria in many instances assist in the breaking down of proteid matter but whether the less complex substances produced in this way can be, and are, utilised by the body at large for its nutrition appears to be doubtful. It has, however, been shown that in life under completely aseptic conditions the fæces do not contain phenol, cresol, indol, skatol, or pyrocatechin, substances found in the fæces of animals living under ordinary conditions. Dr. Lazarus-Barlow sums up the whole question by saying that "at the present time there is a tendency to believe that although the bacteria in the alimentary tract play an extremely important part in inducing intestinal putrefaction, they only act in this direction and do not produce bodies which are utilised by the body to its advantage."

Diseases of the Mouth, Pharynx and Œsophagus are ably dealt with by Dr. Bertram L. Abrahams and this section contains much information with regard to the diseases which may affect those organs.

The portions of the volume which are devoted to a consideration of the Diseases of the Stomach and Intestines have been written by Dr. Allchin. The observations on etiology and pathology are full and complete, containing the most modern views on those subjects. Then follow some extended remarks on the general symptomatology of gastro intestinal disease which will well repay perusal. The symptomatology and treatment of the individual diseases affecting these organs are considered seriatim. We question whether it is a good plan to separate causation and pathology so entirely from the clinical aspect of disease as is entailed by the plan thus adopted. If, for instance, a reader wishes to obtain information on "gastric" or "peptic" ulcer he will have to search in three separate sections before he can attain his object. We are of opinion that the old method of considering the various aspects of each malady (etiology, pathology, symptoms, and treatment) under the heading of that particular disease is to be preferred. It is certainly more convenient for reference and less confusing to the student.

The article on the Physical Examination of the Stomach and Intestines and the Analysis of the Gastric Contents is by Dr. Bertrand Dawson and in it are described the modern methods which are employed as aids to diagnosis in gastric and intestinal affections.

The Diseases of the Liver are considered by Dr. R. G. Hebb and Dr. Alexander Crombie. The article on Hepatic Abscess is a particularly interesting one and the etiology is discussed in a most instructive manner. It is shown that although the maximum frequency of this disease corresponds to a zone comprised within the isotherms of 75° and 80° F., yet heat has probably only an accessory influence and the essential cause of the greater seasonal prevalence is the *relative prevalence of dysentery at the same seasons*, for all hot countries are not equally noted for the occurrence of hepatic abscess. Attention is also drawn to the influence of race. A comparison of the returns of the army of India shows that the mortality from this affection is thirty-two times as great among European as it is among native troops, and this notwithstanding the greater prevalence of dysentery among native soldiers. The influence of age, sex, length of residence in the affected district, alcohol, and chill, and the causal relationship of dysentery and other septic foci in the intestines are also duly commented on.

Dr. W. Hale White writes on Diseases of the Peritoneum. In considering the treatment of tuberculous peritonitis the question as to the performance of laparotomy naturally receives full attention. Dr. Hale White arrives at the conclusion which is now generally held—namely, that the best results are obtained in those cases in which there is a large amount of ascitic fluid free in the peritoneal cavity. It is true, as he points out, that these are just the cases which give the most favourable results when treated without the intervention of the surgeon but on the other hand they are the cases in which the operation is easiest and he therefore urges that as the mortality as a result of the operation is in all cases so low laparotomy should be performed on such cases if circumstances prevent fresh and abundant food from being satisfactorily made use of or if, these having been tried, the progress is slow. We quite agree with him that the cases in which operation is most valuable are those in which there are much ascites and some fibro-caseous change in the peritoneum but in which the adhesions are not numerous or dense enough to prevent the evacuation of the fluid.

Dr. J. H Bryant contributes a short article on Diseases of the Abdominal Vessels.

Diseases of the Kidneys are considered by Dr. J. Rose Bradford. His observations, though brief, are perhaps the most interesting in the volume. In dealing with the etiology of renal disease he draws attention to the fact that it has long been recognised that certain affections of the kidney, as for example some forms of Bright's disease, have in many instances a toxic origin, but it is only recently that the view has gained ground that all forms of so-called nephritis and probably every variety of Bright's disease have a similar origin. Dr. Bradford enters into a discussion as to the nature of these toxic substances and we can recommend to our readers a careful study of his remarks. He is a strong supporter of the value of milk in the treatment of chronic Bright's disease and recommends that when uræmic symptoms are present or when dropsy occurs the patient should be put to bed and kept on a rigid milk diet until the urgency of the symptoms has subsided.

The description of the Diseases of the Ductless Glands is divided between Dr. Sidney Coupland and Dr. Abrahams but, as the most important diseases in which these glands are involved have been already dealt with in the earlier volumes of this manual, this article is a short one. It contains, however, valuable information on diseases of the spleen, lymphadenitis, and tuberculosis of the lymphatic glands. Diseases of the thymus gland are also discussed.

Diseases of the Throat and Nose. By CHARLES HUNTOON KNIGHT, M.D., Professor of Laryngology, Cornell University Medical College; Surgeon, Manhattan Eye and Ear Hospital, Throat Department, &c. With 147 Illustrations. London: Rebman, Limited. 1903. Pp. 423. Price 13*s.*

AFTER a careful perusal of this work we have no hesitation in congratulating Dr. Knight on the results of his labours, for the book is one which commends itself equally to the specialist and to the general practitioner who wish to obtain sound information on the subjects of which it treats. The author's diction is easy and his style is simple and the various conditions which are matter of dispute have the current theories relative to them clearly and lucidly explained. The anatomy and physiology of the nose are briefly but sufficiently dwelt upon and—rightly we think—the physiology of the nose is curtailed and reduced to such statements as are necessary to guide the medical man in his attempts to restore the nasal passages to an approximately normal condition. Dr. Knight next deals with the methods of examination and the instruments necessary for this purpose. This section is, perhaps, too brief and the suggestion that sunlight should be utilised for examination clearly shows that the author has never been subjected to the inconvenience which results from the use of such a powerful illuminant.

The next chapter, which treats of Acute and Chronic Rhinitis, is especially good from the clinical point of view. The pathological histology, however, is not so minutely detailed as was to be expected in a book of this size and description. We next find an account of Atrophic, Membranous, Caseous, and Purulent Rhinitis. Atrophic rhinitis is described as a necessary corollary of pre existing inflammation, one of the few statements with which we are inclined to disagree. If Dr. Knight had perused the admirable paper by Professor Moure, read at the International Congress of Medicine held at Madrid last year, together with the other papers contributed on this subject, we think that he would have recognised that there exist developmental errors in the nasal cavities which are responsible for a proportion of cases of atrophic rhinitis. With this exception, and especially in the treatment of this disease, Dr. Knight's recommendations are most happy. In membranous rhinitis, which is very briefly considered, the impression given is that the pseudo-diphtheritic bacillus is almost invariably present. Caseous rhinitis has sufficient attention devoted to it, a point not usually observed in books of this description. Diseases of the accessory sinuses and their treatment are treated in a way to leave but little room for adverse criticism, though we should have liked to see some reference to the methods of operation adopted by Killian. Especially valuable are the remarks on the sources of error in transillumination. In septal operations Asche's method, where it is suitable, has Dr. Knight's approbation. In nasal polypi we find the pathological standpoint fully investigated. Neoplasms—benign and malignant—specific disorders, epistaxis, and nasal hydrorrhœa receive adequate treatment. In the description of hay fever we notice that Dr. Knight does not mention the serum treatment, which has within the last 12 months been prominently brought before the profession. In Diseases of the Pharynx the adenoid operation is very fully described. There is an excellent, though brief, description of Vincent's angina. The last section is devoted to the Larynx. In the chapter on Anatomy and Physiology, the character of the voice is said to be modified by the changes taking place in the vocal cords, the varying size of the glottis being left out of consideration. The methods of examination and the general therapeutics are again rather too briefly considered, for if instruction is needed that instruction should be full. In the account of acute laryngitis we are a little surprised to see that the influence of nasal obstruction is not touched upon. Chronic laryngitis in all its forms is grouped under one heading. Neoplasms, especially benign, receive a very excellent description and here we find that the influence of nasal obstruction used in its widest sense—that is to say, including post nasal adenoids—is fully recognised as an indirect cause in their development. Malignant disease of the larynx is very carefully described, the subject being brought fully up to date; and tuberculosis of the larynx receives an amount of consideration which is amply justified by the frequency and the importance of the disease. In his otherwise excellent account of the clinical appearances noted in this pathological condition Dr. Knight says that the surrounding parts of an ulcer are pale. This, however, is not usual. Under the heading of treatment it is recommended that the patient should be kept in a uniform temperature, a suggestion which is not entirely borne out by those experienced in the open-air treatment of consumption. In specific disease of the larynx, while all other conditions receive full recognition, stenosis is dealt with in one short sentence. Neuroses, laryngismus stridulus, paralyses, and the presence of foreign bodies receive attention.

This work, admirable in its production, will be of great value to students and practitioners of general medicine and in directing their attention to it we have confidence that they will find it most helpful and instructive.

A Narrative of Medicine in America. By JAMES GREGORY MUMFORD, M.D., Assistant Visiting Surgeon to the Massachusetts General Hospital and Instructor in Surgery in the Harvard Medical School. London and Philadelphia: J. B. Lippincott Company. 1903. Pp. 508.

THIS book, which is dedicated to Professor William Osler, is a narrative dealing with medicine and the medical profession. The author's object has been to take some of the conspicuous American physicians of each era in their proper sequence, to tell the story of their lives and their doings, and thus to illustrate the whole history of medicine in America by a series of pictures. He hopes that the story will show the reader something of the meaning of medicine and of the life of its votaries. The narrative practically ends with the Civil War or about the middle of the last century, as for obvious reasons it has seemed best not to bring it down to the present day. Chapters are, however, added on Ether, on the Founding of the American Medical Association, and on Some Tendencies in Modern Medicine. In the introduction the author briefly glances at the contemporary conditions, political and scientific, in Great Britain, which the early immigrants called "home," to see on what bases English and American medical men of the seventeenth and eighteenth centuries had to build. The age was not a great one for scientific progress, but progress there was, and our profession struggled out of an

Egyptian darkness towards the present light. For the purpose of the narrative the colonial days of America are divided into two eras which correspond roughly with two centuries: the seventeenth century, a time of colonisation, struggle, and privation; and the eighteenth century when towns were being built, when commerce was beginning to thrive, and schools and colleges were appearing in the land. The medical history of the one era is quite distinct from that of the other. To the first belongs the practice, remote and inadequate, of Elizabethan England; to the latter the wider knowledge of American-born men and the early attempts to combine the wisdom and teaching of the Old World with the changed experience of the New.

The book deals not only with the evolution of the medical man but with the inception and development of American hospitals, schools, and universities. In the early history of American science great names are lacking and great events as well, yet in so far as the men of those days stirred up the "Assembly" to pass laws regulating practice they were wise in their generation and did good service. The truth of what Dr. J. S. Billings has said of his country is demonstrated in these pages. In "A Century of American Medicine" he wrote: "We have had, and still have, a very few men who love science for its own sake, whose chief pleasure is in original investigations, and to whom the practice of their profession is mainly, or only, of interest as furnishing material for observation and comparison. ...... Of the highest grade of this class we have thus far produced no specimens: the John Hunter, or Virchow, of the United States has not yet given any sign of existence." Many of the stories told in Dr. Mumford's book are not new but the method of the telling is, we think, just and honest and the author's meaning is conveyed in a way which charms the reader.

Some 30 pages are devoted to the tale of the famous discovery of the anæsthetic properties of ether, America's greatest contribution to medical science in the last century. The words of the venerable Jacob Bigelow uttered at the "Semicentennial of Anæsthesia" bring this section of the book to a most fitting conclusion.

Before finishing this retrospect the author notes the gradual levelling up of the masses of the profession and remarks that the country districts are not being properly furnished with medical men; whereas, on the other hand, in the cities the supply of highly trained practitioners greatly exceeds the demand. The available statistics show that only about one-fifth of the men who have passed through the Harvard school during the years 1892–1901 are pure specialists and that in this conspicuous group of highly trained men there appears no increasing tendency to abandon "general practice." Among the "pleasures of the doctor's life" the author writes of the fascination of work and study, of the ever-present sense of something accomplished, of the stimulation of great responsibility, and of the study of the strength and weakness of humanity—the latter an inexhaustible, fascinating, pathetic, sometimes contemptible, and often terrible field, which makes its votaries either sneering sceptics or, more often we hope, great-hearted philosophers. The last chapter of the book is one which will bring pleasure to any member of the profession who peruses it. Dr. Mumford has given to us a solid contribution towards the history of the profession in the New World.

Milk: its Production and Uses. By EDWARD F. WILLOUGHBY, M.D., D.P.H. Lond. London: Charles Griffin and Co., Limited. 1903. Pp. 259. Price 6*s.*

THERE is no doubt that if every farmer and dairyman knew the ways and means by which milk may become a vehicle or a factor in the spread of disease greater care would be exercised in the clean production of milk and a purer supply would be the outcome. This book aims at being a manual by which information on the points concerning the relationship of milk and disease may be conveyed to the cowkeeper and dairyman. That is a very excellent object and the author has done well to emphasise his intentions. The chapters on breeding, on the management of the cow, and on the construction of cowsheds and dairies give evidence of the author's practical acquaintance with the subject but we think that the sections on milk analysis might have been well left out. It is quite a separate department and one which has little concern for the breeder or keeper. Besides there is a superabundance of handy books on the composition and analysis of milk, on the question of preserving milk, and on bacteriological methods of examination. Chemical analysis has nothing whatever to do with the supply of milk free from disease-producing entities. The author is the inspector of the farms of, and general scientific adviser to, a large dairy company supplying milk to the metropolis and certain suburbs, and the experience which he gains in this capacity must be valuable and should be helpful to those who are anxious to provide a really sanitary milk-supply.

LIBRARY TABLE.

The Causation and Prevention of Malarial Fevers: a Statement of the Results of Researches. Drawn up for the use of Assistant Surgeons, Hospital Assistants, and Students. By Captain S. P. JAMES, M.B. Lond., I.M.S. Issued under the authority of the Director-General of the Indian Medical Service. Second edition. Calcutta: Office of the Superintendent of Government Printing, India. 1903. Pp. 52. Price Re. 1, or 1*s.* 6*d.*—The first edition of 5000 copies of this pamphlet was, the Director-General of the Indian Medical Service tells us, soon exhausted. In preparing a second edition Captain James has enlarged the scope of the work so as to make it an easy introduction to the study of malaria. We have read this little publication, which is full of pertinent information and excellently illustrated, with both interest and profit and may congratulate Captain James on having performed a very useful work. It is quite what it pretends to be and gives a clear, well-arranged, and capital *résumé* of the subject and may be accepted and used as a scientific and practical guide by those for whom it was designed.

Lehrbuch und Atlas der Zahnheilkunde mit Einschluss der Mundkrankheiten. (*Manual and Atlas of Diseases of the Teeth and Mouth.*) By Dr. Med. GUSTAV PREISWERK. Munich: J. F. Lehmann. 1903. Pp. 352, with 152 Illustrations. Price 14 marks.—This volume includes those special sections of anatomy, physiology, and pathology which have a direct bearing on dental surgery and the author has within the comparatively small space at his disposal succeeded in producing a useful text book. In the early chapters the anatomy of the teeth and of associated parts is described, the text being accompanied by serviceable illustrations. In the following chapters the various affections of the buccal mucous membrane and the more common tumours affecting the jaws are considered and there is a short, even perhaps too meagre an account of the bacteriology of the mouth. The author might with advantage have extended the account given of abnormalities in position of the teeth and a recently published book might have been expected to contain more up-to-date methods of treatment. In dealing with the pathology of the pulp the classification of Arkövy and Rothmann is adopted. The different affections are clearly described and some excellent illustrations are given. Throughout the book the technique of operative measures is only briefly treated and in some instances the methods advocated are open to adverse criticism.

Précis d'Anatomie Dentaire. By J. CHOQUET. Paris:

F. R. de Rudeval, Éditeur. 1903. Pp. 496, with 195 Illustrations. Price 8 francs.—As a contributor to current dental literature M. J. Choquet is well known to English readers and anything from his able pen is always welcome. The present volume is a most happy effort and should prove useful to students and practitioners of medicine. The opening pages are devoted to a general consideration of the teeth of the animal kingdom and this is followed by the anatomy of the mandible and maxilla. The author brings clearly home to the reader the fact that these bones differ very much in shape in different races and he introduces on p. 32 a most instructive illustration showing the variation in the form of the mandible of individuals of the same age but of different races. Again, in the description of the maxillæ he describes and figures three types of arches—namely, hyperbolic, parabolic, and v-shaped. The importance of a thorough knowledge of the anatomy of the antrum is essential on account of its bearing on the treatment of antral suppuration and we should therefore expect to find a full account of this sinus. M. Choquet has, however, treated the description in barely two pages and only gives two illustrations—one in a human subject and the other in a gorilla. In future editions we hope to find this defect remedied. In the chapter "Rapports des deux Maxillaires" numerous examples of partially edentulous dentures are given and the student is enabled to learn the anatomy of such conditions. The superficial anatomy of the individual teeth is thoroughly described and numerous illustrations are given, but we fail to find a satisfactory account of the shape of the pulp chambers, more especially with regard to their relation to the contours of the teeth. It is true that figures are given showing the distance of the cornua of the pulp from the mesal and distal angles of the teeth at different ages but these are of little value. In the description of the enamel reference is made to the chemical composition, the analyses of von Bibra being followed. These give 3·59 per cent. of organic matter in the enamel of man and a larger quantity in that of woman. Mr. C. S. Tomes's researches on the point seem to have escaped the notice of the author. This investigator has shown that the enamel is practically devoid of organic matter and that the constituent usually taken as such is in reality water of crystallisation, while in the dentine a large part of the matter previously considered organic is also water of crystallisation. The chapter on the calcification of the teeth is good and descriptions are given of dentures in children of two, four, five, and seven years of age. The figures given of the dates of eruption are in accord with those usually considered as correct in this country but it is quite possible that different races may produce different data. The value of the book would be enhanced if the micrographic illustrations were better; the fault seems to lie in defective photography rather than in the production of the "process blocks."

A Pocket Dictionary of Hygiene. By C. T. KINGZETT, F.I.C., and D. HOMFRAY, B.Sc. Second edition. London: Baillière, Tindall, and Cox. 1904. Pp. 112. Price 2*s.* 6*d.*—This little book—it measures four and three-quarter inches by three inches—is certainly handy for the pocket, and the chemical and hygienic information is accurate and useful, but in places the medical information is, to put it mildly, misleading. Thus, under the word "Measles" we are told that the mortality is usually low, although occasionally there is an outbreak in which it runs up to 40 per cent. This statement is insufficient. Again, under the word "Hæmorrhage" the following passage occurs which to our minds is hopelessly confusing: "When an important blood vessel in the arm or leg has been ruptured the best way to prevent violent hæmorrhage ...... is to hold the limb up and bind it round as tightly as possible just above the rupture." No distinction is made here between arterial and venous hæmorrhage and the uninstructed person, we should say, on reading these directions would in the case of a wounded artery apply the bandage in exactly the wrong place. Again, under the word "Poisons" emetics are recommended in the case of alkalies, a course which might prove fatal in a patient who had taken a corrosive alkali. Before a third edition comes out we recommend the authors to have the medical portions of their dictionary revised.

The Insurance Blue-book and Guide, 1903–04. London: Dawbarn and Ward. 1903. Pp. 459. Price 2*s.* net.—This handy publication contains an immense amount of information concerning insurance. Amongst other items are a directory of insurance offices, tables of mortality and expectation of life, the accounts of nearly all insurance offices, a chapter on the legal aspects of insurance, and instructions for obtaining probate or letters of administration. The book is well arranged and clearly printed.

A Few Facts and Figures concerning Vaccination and the Fallacies of Antivaccinators. By J. HEDLEY MARSH, M.R.C.S. Eng., L.R.C.P. Lond. Macclesfield: Claye, Brown, and Claye. 1903. Pp. 56.—This pamphlet is a reprint of letters contributed to the columns of the *Macclesfield Courier* during October and November, 1903. They were written by Mr. Marsh to controvert the statements made by Mr. Harold Whiston, an antivaccinationist, in a lecture delivered in a dissenting chapel, and other statements made by other antivaccinationists in the columns of the *Courier.* The antivaccinationist, however, is like the deaf adder of scripture; he will not hear. Mr. Marsh's array of facts should convince anyone but they will not convince antivaccinationists.

New Inventions.

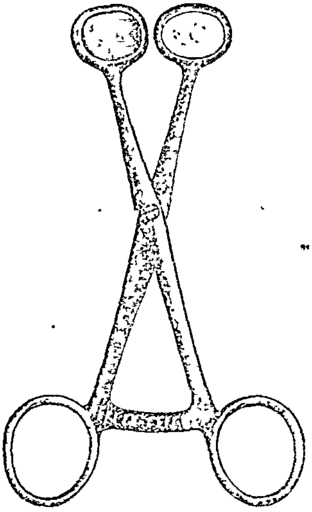
A TROPICAL CLINICAL THERMOMETER.

IT frequently happens that a surgeon in the Gambian Protectorate has to take the temperature of a patient when the atmospheric temperature is greater than that of the patient. For example, from May 1st to June 19th, 1902, out of the 50 days in 26 days (say 50 per cent.) the temperature in the shade from noon to 3 P.M. was above that of normal blood heat. During ten of those days it was over 100° F. and on three occasions it reached 105°. Now given an atmospheric temperature of, say, 104° and a patient with a temperature of, say, 101°, the question arises, How is one to record it with an ordinary clinical thermometer? which is of course registering 104°, the atmospheric temperature, and cannot be shaken down below that. For this purpose Mr. F. Darton, manufacturing optician, of 142, St. John-street, Clerkenwell, London, E.C., has made at my suggestion a tropical clinical thermometer having the following points: (1) a shaft six inches long; (2) an open scale; (3) non-prismatic; (4) no stricture or bend to prevent the mercury running down; (5) a large calibre tube; and (6) a vacuum bulb at the distal end to take up 4° or 5° of expansion. The advantages of this thermometer are: (1) it can be read in the patient's mouth or axilla without removal; (2) open scale for the same purpose; (3) non-prismatic so as to be read at any angle it may have turned towards you; (4) no stricture or bend (this practically makes it a minimum thermometer, so that when taken from an atmosphere standing at, say, 104° the mercury will drop to the cooler temperature of the patient at, say, 101°); (5) the large calibre of the tube facilitates this; and (6) the vacuum bulb at the distal end to take up 4° or 5° of expansion is to prevent bursting. Government travelling commissioners have reported to me that their ordinary clinical thermometers have sometimes burst, owing to (as occasionally happens) the temperature rising to 110° and over. This thermometer will be suitable to all high tropical temperatures. It will be equally suitable in temperate climates and as it requires no shaking down it would save time in a hospital ward, rising and falling to each patient's temperature. The six-inch shaft is more suitable for reading axillary temperatures *in situ* but a four inch shaft can also be had.

F. A. BALDWIN, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A.,
Protectorate Surgeon, McCarthy's Island, Gambia, West Africa.

ENTROPIUM FORCEPS.

AT my suggestion Messrs. Arnold and Sons have constructed a pair of entropium forceps as figured in the accompanying illustration. It will be noticed that they are larger than the old-fashioned instrument and that they are fixed by a rack instead of a screw. This facilitates their application and enables an assistant to hold them in position more easily. The fenestrated blade is made to fit into a groove round the flattened blade and the latter is made slightly convex so that it will force the tissues above



the scalpel cor
may be more
detachable jo
fenestrated blade is concave instead of angular. Anyone who has used the old-fashioned instrument must have experienced some of the difficulties I have indicated and as the removal of a tarsal cyst is an operation which many members of the profession undertake I hope that this modification may be of use.

I am indebted to Messrs. Arnold for the careful manner in which they have carried out my idea.

J. LIONEL STRETTON,
Senior Surgeon, Kidderminster Infirmary and Children's Hospital.

A HEALTH TENT.

Messrs. S. Wilson and Co., of Bedford-street, Belfast, have sent us an illustrated description of their "patent health tent," in which there are no poles visible when the tent is erected and an air space six inches wide is provided between the inner and outer layers of canvas for the purposes of reducing variations of temperature. A centre pole is not used. A special feature of the tent is stated to be the employment of stretchers and of cross-stays connecting the vertical poles together in such a manner as to be adjustable lengthwise. These stretchers are, in fact, strong spiral springs and in this way the canvas is firmly held both in wet weather and in dry. The makers believe that the tent will be found useful in the open air treatment of tuberculosis and in the isolation of cases of infectious disease.

ST. BARTHOLOMEW'S HOSPITAL.

A MEETING convened by the Lord Mayor was held at the Mansion House on Jan. 26th in furtherance of the appeal for funds for St. Bartholomew's Hospital for the erection of new buildings.

The LORD MAYOR, who presided, called upon Sir Trevor Lawrence, the treasurer of St. Bartholomew's Hospital, to make a statement to the meeting.

Sir TREVOR LAWRENCE said that he was authorised to state that the rebuilding appeal had the sanction and sympathy of the Prince of Wales, who was president of the hospital. The question of the site of the hospital had been dealt with by the Mansion House Committee and that committee had decided in favour of the retention of the hospital on its present site. One of the witnesses before the committee was the Chief of the City of London Police and he stated that of all the accidents and cases of sudden illness occurring in the City 65 per cent. were taken to St. Bartholomew's Hospital. Sir Trevor Lawrence then read the following passage from the *Times* of Jan. 16th:—

> The maintenance without shrinkage of the maternity department,
> strongly contrasting with
> King's College, shows that
> still contains a large resid
> perhaps excepting that of t
> fruitful of accidents than

In regard to the scheme involving partial removal of the hospital Sir Trevor Lawrence said that it seemed to him a most undesirable suggestion, because it would cause great difficulty in the treatment of patients and would destroy the medical school, the maintenance of which was a matter of the utmost importance. The value of the site in his opinion had been very largely and very seriously exaggerated. In the opinion of experienced valuers the price was much less than had been estimated by the advocates for the removal of the hospital. He contended that the mere question of the value of a site did not comprise the whole problem. Money considerations should not be put before the interests of a great institution carrying on a work of mercy and charity. It had further to be remembered that the majority of the patients were too poor to afford the money or time to go to a distant hospital in the suburbs. Referring to the population shown by the last census in the proximity of the hospital, he pointed out that the census was taken on a Sunday night and the great number of people who worked in the neighbourhood during the day-time were not taken into account. During the last 50 years no fewer than 7,000,000 patients had been treated at the hospital and in the out-patients' department during the first three weeks of this year the number of attendances had been 15,247. Dealing with the question of the proposed new buildings Sir Trevor Lawrence said that the wards were somewhat antiquated and immediate attention was required in certain departments, the most pressing need being first a new casualty and out patients' department with separate accommodation for ophthalmic, orthopædic, skin, throat, ear, electrical, dental, and gynæcological cases. A home for 240 nurses and 80 female servants was wanted. Sir Trevor Lawrence concluded by giving a list of the new buildings required for which a sum of £438,000 would have to be found.

The BISHOP of LONDON then moved the following:—

> That this meeting, having heard the statement of the treasurer of St. Bartholomew's Hospital, cordially approves of the decision of the governors to reconstruct the hospital on its ancient City site, extended as it has recently been by the addition of one and a half acres.

He said that the appeal made that day was made by the pioneer hospital of the whole country which had done splendid work in the cause of humanity for 800 years. In all parts of the world there were many men who ought to send a contribution to the rebuilding fund. What they wanted was the best hospital that could be turned out for the City of London and he pleaded earnestly that the generosity of the citizens of London should give St. Bartholomew's what was required.

Sir WILLIAM CHURCH, in seconding the motion, said he had spent 40 years at St. Bartholomew's Hospital and during that time many great improvements had been made by the governors of the hospital in the wards and in the service of the institution. Want of space had alone prevented structural changes being carried out adequate to the ever-growing importance of the work done in the casualty, out-patient, and other departments of the hospital. St. Bartholomew's Hospital had recently had the opportunity of extending its borders and could appeal with confidence to the City of London and to the public for the necessary help to improve the condition under which it had so long been labouring. They had heard certain objections raised in regard to the appeal being placed before the meeting without any detailed plans of the rebuilding having been furnished. In his opinion such objections could not be seriously advanced. Surely they could trust the governing body of the hospital and the medical staff to see that in providing for present wants nothing would be done that would in any way hamper the future reconstruction of the hospital. It had been argued that St. Bartholomew's Hospital should be moved because its site was a veritable gold mine, but the value of that site could not be known until it was put on the market for sale. There was the further consideration that towards that site every day there was an influx of from 30,000 to 40,000 workers to premises in the closest proximity to the hospital and they knew that accidents and sudden illnesses occurred during the working hours of the day more often than when people were sitting comfortably at home. They had been told that 65 per cent. of the accidents in cases of sudden illness in the City were sent to St. Bartholomew's Hospital and that number would be increased by the removal of King's College Hospital. Continuing, Sir William Church said that he particularly desired to remove an impression that had arisen from injurious and misinformed statements that the present wards were so out of date as to be prejudicial to the health of the patients. That, he assured them, might be dismissed from their minds entirely, for the results obtained by the medical staff were as favourable as those shown by the most up-to-date hospitals. He considered that the removal of the hospital to another site would destroy the medical school and he reminded them that if a medical school was not attached to a large hospital there must be a large increase in the expenses of the treatment of patients. There was the further point that the absence of the medical school would remove that beneficial rivalry with other schools of medicine in attaining the best possible treatment for the relief of suffering and pain. They were not ungrateful to the City of London for the help that had been afforded to the hospital when the present wards were erected some 150 years ago, and they confidently looked to the City of London and the public to come to their aid again so that St. Bartholomew's Hospital might remain in the future, as it had been in the past, one of the great centres of the kingdom for the relief of pain, for the acquirement of medical knowledge, and for the advancement of medicine and surgery.

Mr. JOHN TWEEDY, President of the Royal College of Surgeons of England, in supporting the motion, said that he was one of those who was disposed at first to consider favourably the proposal for the removal of the hospital to another site, but after reading the report of the Mansion House Committee he had altered his views. He pointed out that in addition to the arguments put forward there was much to be said for the maintenance of the historical tradition of the hospital and the satisfaction of historical sentiment. He asked them, What would New York not give to have within its boundaries an institution that for nearly 800 consecutive years had been carrying on one of the noblest works of charity? What would any city in any part of the civilised world not give to possess a site hallowed by its associations with Harvey and a hospital made memorable as a school in which John Hunter received his surgical education? He felt certain that the City of London would not allow these sentiments to pass by unheeded.

Dr. S. J. GEE, speaking on behalf of the medical staff, described the active growth which was taking place in all departments of the hospital and contrasted the number of the staff in 1868 with the number of the staff at the present day. He also urged that the removal of the hospital would be an unwise proceeding.

The LORD MAYOR then put the motion to the meeting when it was passed unanimously.

The next motion was proposed by Mr. ALBAN GIBBS, M.P., and was as follows:—

> That this meeting pledges itself to support the governors of St. Bartholomew's Hospital in their appeal for the funds necessary for the reconstruction of the hospital and earnestly commends to the generosity of the public this the first appeal which the hospital has made for 150 years.

This was seconded by the MASTER of the Mercers' Company who promised that the appeal would be considered in a liberal spirit by the court of his Company.

The CHIEF RABBI also supported the motion and described how in visiting his own poor in the wards of St. Bartholomew's he was greatly struck by the kindness and consideration with which they were treated.

Sir WILLIAM HART-DYKE, M.P., also supported the motion and was followed by Mr. A. A. BOWLBY, who said that he addressed the meeting in order to emphasise the fact that the staff of the hospital were absolutely unanimous in supporting the present proposal. Dr. Gee had spoken for the medical side and what he said was equally true for the surgical side. The difficulty was the want of space in which to do the work.

Upon this motion being put to the meeting by the LORD MAYOR it was declared carried with two dissentients.

After Sir WILLIAM TRELOAR had made the announcement that the sum of £40,000 had been received in cheques and promises towards the fund, a vote of thanks to the Lord Mayor for presiding was proposed by the MASTER of the Merchant Taylors' Company seconded by the Rev. R. J. CAMPBELL, supported by a speech from Mr. J. LANGTON and carried with acclamation.

The LORD MAYOR briefly responded and the proceedings then came to an end.

Looking Back.

FROM

THE LANCET, *SATURDAY*, JAN. 28, 1826.

Yellow Fever.

While the medical world continues to be disturbed by that irreconcileable subject—that *bugbear* to the profession—Contagion, it is with no little pleasure that we lay before our readers the Report of the French Academy of Sciences on this hacknied question. The cool and dispassionate manner in which it has been investigated does credit to the members, and is well calculated to conciliate the absurdities of the *Ayes* and the follies of *Noes*.

M. Dupuytren read a report on the memoir of MM. Lassis, Costa, and Lasserre, relative to yellow fever, and some new experiments on the contagious nature of the malady. He commenced by showing the opposite opinions entertained as to the way in which yellow fever, as an epidemic, is thought to be propagated.

"In the theory of contagion," observed M. Dupuytren, "it is allowed that the malady, carried to its height, is capable of giving rise to a *miasm*, a sickly principle, a true germ, which escapes from the bodies of the sick, and preserves the power of reproducing the malady, with all its concomitant symptoms."

"In the theory of infection, on the contrary, it is contended that the malady can never propagate itself but under the influence of causes which are capable of producing it primarily, as heat and moisture, impure air, putrid exhalations, in places where the air cannot renew itself easily; these are considered as causes always indispensable for the reproduction of yellow fever."

"If the germ, or *effluvium* of the contagionists," continued M. Dupuytren, "really exists, that man will be rendering an incalculable service to mankind who will, in a clear way, point out the mode by which we can assure ourselves of its presence."

"It is not necessary to say, that in accordance with the idea which they form of the malady, diametrically opposite measures are called for to prevent the propagation of its ravages; sequestration effected by every sort of means, sanitary cordons, and lazarettoes, are a consequence of the theory of contagion, whilst the dispersion of the sick ought to be directed by the exclusive partisans of infection."

M. Dupuytren concluded these general remarks by observing, that if the theory of infection appeared more simple and seducing, since it admits but of one cause, that of contagion seems better calculated for the explanation of detailed facts.

LONDON: SATURDAY, JANUARY 30, 1904.

New Facts concerning Malignant Growths.

EVERY new fact relating to the vital processes of malignant growths is sure of receiving a hearty welcome from all, even though at first sight there may seem to be no very close connexion between the new fact observed and the etiology and treatment of cancer. But the more we know of malignant growths the more likely are we to arrive at exact ideas as to their causation and a rational system of therapeutics. Within the last few weeks two papers of great value in the study of malignant growths have been read before the Royal Society of London, and, though opinions may differ as to the exact bearing of the facts communicated, there cannot be any doubt of the importance of the observations recorded. The first of these papers was read on Dec. 10th of last year and was written by Professor J. B. FARMER, F.R.S., Mr. J. E. S. MOORE, and Mr. C. E. WALKER. It was a record of a large number of careful observations on the intranuclear changes occurring in those cells of malignant growths which are undergoing multiplication. It was entitled "Resemblances exhibited between the Cells of Malignant Growths in Man and those of Normal Reproductive Tissues." It is unnecessary to go with more detail into the paper in question, as a full abstract was published in our columns,[1] while a discussion of the mitotic changes which occur in the division of a nucleus of an ordinary somatic cell would be quite outside the scope of this article. Suffice it to say that the phenomena in all somatic cells are alike, but that in the cells which are developing into ovaries or testes the mitotic changes are strikingly different, forming the so-called "heterotype mitosis." Now Professor FARMER and his collaborators—and the work was genuine collaboration—showed that in malignant growths the mode in which division of the nucleus is effected differs from that exhibited by somatic cells and resembles very closely that found in developing reproductive tissue. That is to say, there is heterotype-mitosis in malignant growths. Benign growths show homotype mitosis, as is found in ordinary somatic cells, and the difference, now scientifically recorded, may obviously be of value in diagnosing between a simple and a malignant growth. It is curious to find that an approach to the idea that there was some relation between the activity of malignant growths and "germinal epithelium" was made several years ago. In 1896 Dr. G. T. BEATSON read a paper before the Edinburgh Medico-Chirurgical Society in which he suggested that "cancer consists in the epithelium of the part affected taking on the active proliferation which is a marked characteristic of the germinal epithelium" and that "there seems a reasonable ground for thinking that the active processes seen in a cancerous tumour are best explained by regarding the epithelium of the part as having taken on the properties and the powers of the germinal epithelium." As the outcome of this theory Dr. BEATSON performed on several patients with inoperable malignant disease the operation of double oöphorectomy. In a certain proportion of the cases great improvement followed, and in some apparent recovery. Varying results have been obtained by different operators who have applied this method of treatment in such desperate cases, and on the whole the opinion exists that in some cases of cancer the removal of the ovaries does exert a favourable influence. Without pressing unduly the similarity between the views of Dr. BEATSON and those set forth in the paper read at the Royal Society we draw attention to the resemblance as interesting and noteworthy. Dr. BEATSON'S letter on this subject will be found in our issue of Jan. 2nd and the reply of Professor FARMER and his colleagues appeared a fortnight later.

A second paper of equal importance to medical readers on the pathology of cancer was read at the Royal Society on Jan. 21st for the authors, Dr. E. F. BASHFORD and Dr. J. A. MURRAY. Dr. BASHFORD is the general superintendent and director of the central laboratory of the Cancer Research Fund of the Royal College of Physicians of London and the Royal College of Surgeons of England, and this paper, among the first-fruits of that research, will shortly appear at full length in our columns. Upon several important points in this paper we may dwell in a few preliminary words. In dealing with the significance of the zoological distribution of cancer and the nature of the mitoses Dr. BASHFORD and Dr. MURRAY apply to the new growths met with among the lower animals the rule laid down by Professor FARMER, Mr. MOORE, and Mr. WALKER with regard to man. A large number of malignant tumours have been examined and tumours from the trout, the mouse, and the dog all showed the character in the mitoses seen in reproductive cells. Thus a complicated sequence of cell changes has been found to be characteristic of carcinoma and sarcoma alike, and this sequence is the same as that which initiates the origin of the sexual generation in plants from the asexual, and is terminal in the history of the sexual cells in animals. Dr. BASHFORD and Dr. MURRAY have found that the malignant growths occurring in domesticated animals and other vertebrates are identical with those found in man, clinically, pathologically, anatomically, and microscopically. Moreover, since the malignant new growths occur in animals under the greatest diversity of habitat, food, and general conditions of life, Dr. BASHFORD and Dr. MURRAY hold that such external conditions can have but a subsidiary rôle in determining the incidence of the disease, and from this it is concluded that the essential factors must be sought in the potentialities which reside in the cells constituting the living body. A third point brought out in this highly valuable and suggestive contribution to pathological study dealt with the histological changes seen after an attempt to transfer a malignant tumour from one animal to another of the same species. It was found that the new tumour, which arises from the implantation of a portion of a tumour from another animal, springs from the actual cells introduced and not from the part into which the portion of tumour was implanted. Dr. Bashford and Dr. Murray conclude from their researches that "cancer is an irregular and localised manifestation of a process otherwise natural to the life-cycle of all organisms." We may be sure that the work of Dr. Bashford and Dr. Murray will receive the closest attention from all pathologists and biologists, for the significance of such a conclusion, as dictating the direction of future research work, is immense.

---

[1] THE LANCET, Dec. 26th, 1903, p. 1830.

The public, who have read extracts in the daily press from the two papers under consideration, have imagined that we are now measurably nearer a knowledge of the etiology and treatment of malignant disease. Unfortunately this is not so. A direction, apparently of a most valuable kind, for future investigation has been provided. As to the importance of the observations there can be no question, but the conclusions that we may safely draw from the excellent work that has been done would seem to the lay mind rather meagre. Let us review what fresh data we have obtained. We have learnt, first, that the mode of nuclear division observed in most of the dividing cells of malignant growths resembles very closely, or is even identical with, that seen in the reproductive tissues and differs greatly from the mode of division in ordinary somatic cells; secondly, that this form of mitosis is found not only in malignant new growths occurring in human beings but also in all the malignant growths examined which occurred in lower vertebrates of many species. What conclusions may be drawn from these data? To say that because the mitotic changes in cancer resemble very closely the mitotic changes in reproductive tissue therefore there is necessarily an identity in the physiological processes of these two tissues is a faulty syllogism; for as we know nothing of the true meaning of the nuclear changes in cell division we are utterly unable to predicate anything as to the interpretation of the nuclear changes in malignant growths. Therefore any theory of etiology depending on this resemblance rests on a very frail support. And if we cannot see at present how these recent observations can serve to elucidate the difficult problem of cancer genesis so we are equally unable to draw any very hopeful inferences as to a treatment of cancer which may serve to control this widespread scourge. Nevertheless, every new fact, every new idea, every new aspect of facts already known helps forward the day when we shall understand fully the etiology and treatment, both preventive and curative, of malignant disease. We congratulate Dr. Bashford heartily on the issue from the central laboratory of the Cancer Research Fund of so important an addition to our exact knowledge. He has furnished the governing body, among whom may be found the name of His Majesty the King, with an admirable argument wherewith to charm money from the public pocket.

◆

The Illegal Detention of Lunatics.

A man named Avard was convicted under the Lunacy Act, 1890, at Bearsted in Kent on Jan. 18th and fined £15 with £10 costs for receiving lunatics in an unlicensed house. He had apparently done this for some time, as one of the inmates of this establishment, of whom there were seven, had been there since 1888. Dr. F. P. Davies, medical superintendent of the Kent County Asylum, who, instructed by the Lord Chancellor, had visited Avard's premises, informed the magistrates that he found the bedding used by some of the inmates in an indescribably filthy condition, that there was no provision for safety in the case of fire, that there were only two attendants of any kind, and that he could not ascertain that any medical man had attended any of the persons received. In the circumstances the penalty imposed may be regarded as a light one but the magistrates were evidently impressed with the length of time during which this very undesirable institution had existed without attracting attention. No doubt the Commissioners in Lunacy acted as soon as they were informed, but it is certainly a matter for surprise that no one should have thought it desirable to interfere sooner. The nature of the house and the outline of the provisions of the lunacy law are matters of which, it might be thought, the local police would have some cognisance and in which members of the public might also reasonably be expected to take an interest. Instances of the detention of the insane in unlicensed houses under the care of persons, not only unprovided with any legal title to practise medicine but not even conversant with nursing, are brought to light from time to time. Sometimes the persons so detained are found to have been treated with every care and those charged with detaining them have disputed their guilt on the ground that the mental condition of the patients was not such as to require certification. Two instances of this occurred in the metropolitan district in September, 1901, and in September, 1902, respectively, but in both of these cases the magistrates did not accept ignorance of the fact that a breach of the law was being committed as an excuse and fines were imposed larger than that inflicted upon Avard. Cases such as these present features which show the need for public supervision and inspection whenever the mentally weak have to be provided for.

In most instances the person charged is usually found to have had no medical training and no experience in the tending of the feeble minded. Unfortunate persons, harmless but imbecile, frequently suffering from senile dementia accompanied perhaps by chronic palsy of the limbs, become a burden to their relatives who desire to get rid of the charge of them and at the same time to secure their object with the minimum of expense and publicity. The poor creatures thus afflicted are consequently handed over to someone who is recommended to the relatives by a carefully worded advertisement and afterwards, so long as the small payment agreed upon is maintained, can be conveniently forgotten. When someone, who takes an interest in the welfare of his fellow creatures apart from any personal acquaintance which he may have with them, chances to call the attention of the Commissioners in Lunacy to what is going on it is found that the insane persons have been maintained alive, for that is necessary in order that their keepers may derive an income from them, but that beyond this they have been allowed to live in a state of filth, misery, and neglect, constituting cruelty of the grossest kind.

At the house of Avard it will be noticed there were no precautions against fire, and no doubt had a fire taken place a holocaust would have been the result with the probable consequence of an indictment for manslaughter against AVARD himself. It is not often, no doubt, that institutions so large as his go on for so long unobserved, but at the same time large premises give the idea that a home for the infirm is being maintained and thus act to some extent as a protection to the unlicensed masters of such establishments. The Commissioners in Lunacy must depend for their information upon the goodwill of the public, and members of the public, including medical men, who are not unlikely to be acquainted with the reputation of houses in their neighbourhood, no doubt do a good work in calling the Commissioners' attention to the desirability of inquiry where the treatment of persons helpless on their own behalf is concerned. The Commissioners do not themselves visit the unlicensed house, but the Lord Chancellor or the Home Secretary has power to make an order requiring a specified person or persons to visit a place where alleged lunatics are detained and to make a report. It was in pursuance of such an order that Dr. DAVIES visited the premises of AVARD in the case under discussion, with the result that the inmates are now, it is to be hoped, in institutions where proper care will be taken of them. Where two or three persons only are detained illegally, or only one, observation is less likely to be excited, but the law provides a remedy and the Commissioners in Lunacy are ready to enforce it wherever evidence is obtainable upon which they can act.

◆

The National Hospital for the Paralysed and Epileptic and Organised Scientific Research.

THE appeal in aid of a research fund, which has just been issued by the authorities of the National Hospital for the Paralysed and Epileptic in Queen-square, is one that deserves the earnest consideration of all who are in a position to promote the attainment of the end desired. The hospital in question from its very foundation has occupied a unique position as one in which the advancement of science has been recognised as a primary object of its existence. Originally founded by two ladies, who had witnessed the prolonged sufferings from paralysis of a beloved relative and who desired to prevent the occurrence of similar suffering in others, the hospital received the stamp of its future character from the first appointments made to its medical staff, appointments which included the names of BROWN-SÉQUARD, of LOCKHART CLARKE, and of CHARLES BLAND RADCLIFFE. Besides affording material for their investigations it was the first hospital in London, or probably in Great Britain, to possess the means for adequately conducting and testing various forms of electrical treatment, and it has always been conspicuous for its promptitude in recognising and in rendering available every ray of light which could be thrown upon its proper work by those engaged in other departments of medical inquiry. Ophthalmic surgeons, an aural surgeon, a laryngologist, were from time to time added to the staff, not so much because the departments thus represented would otherwise have been neglected by the physicians and surgeons as in order to provide that nothing should be lost which it was possible for them to supply. It has been long conspicuous as one of the chief centres of cranial and spinal surgery in the metropolis and a pathologist occupies an important position among its officers. With these advantages, it can be no matter for surprise that it has been much frequented by visitors from the continent and from America, or that its out-patient rooms have often been so thronged by post-graduate students as to remind those frequenting them that, just as shoemakers' wives are said to be the worst shod, so the conditions of atmosphere tolerated by medical audiences are often such as could not be conscientiously approved in places of even temporary sojourn for their patients. Nor is it the least among the merits of the institution as now existing that it was lately the arena of a conflict between the lay committee and the medical staff who were determined to recover a position of influence in its management of which they had been gradually and quietly deprived. We need not dwell upon the details of a dispute which will be fresh in the recollection of our readers and it is enough to say that the staff, after enduring all things at the hands of the committee and of its executive officer, were at last completely successful in an appeal to the general body of the governors. The committee was reconstituted with members of the staff forming an integral part of it and with the complete abolition of the sway previously exercised by a non-medical official.

A hospital with these antecedents and abundantly supplied with clinical material of the most varied description would be untrue to its traditions if any slackness concerning research were displayed by the members of its staff, and hence it is not surprising that the pages of *Brain*, the official journal of the Neurological Society, have been largely occupied with accounts of the work done within its walls. To one portion of this work the appeal before us might properly call attention—namely, to the paper on Landry's Paralysis contributed by Dr. E. FARQUHAR BUZZARD to the spring number, and containing an account of a micrococcus which he obtained from a patient dying from the disease in the hospital and from cultures of which he produced an analogous form of paralysis in a rabbit. We possibly do not exaggerate in assigning to this discovery a place equal in importance to that of the discovery of the trypanosoma of sleeping sickness, for the former disease was previously quite as mysterious as the latter and, although not frequent, it has of late years been increasingly observed both in this country and in America. One of the earliest cases recorded in London was communicated to the Clinical Society in 1875 by the late Dr. ANSTIE who attended it in conjunction with the late Sir ANDREW CLARK and who, like him, was not only quite unprepared for the rapidly fatal issue but did not at first recognise that he was dealing with a condition involving danger. Dr. ANSTIE'S paper opened ground so completely new that it elicited no other remark than an expression of sympathy with the father of the patient who was himself a member of the society. No one had a word of suggestion either as to the actual condition or the possibilities of treatment. In contrast with this Dr. BUZZARD is able to draw upon a chronicle of several recently recorded cases, and although he cannot as yet offer any suggestion as to the mode by which the micrococcus obtains entrance into the human body the whole history of science teaches us to expect that the knowledge of causation will be the first step towards the attainment of control. In many other directions the abundant material of the hospital will no doubt admit of being utilised for the benefit of mankind, and the appeal is one which will, we trust, meet with a prompt and sufficient response. It was a saying of FARADAY that new knowledge is frequently passing unrecognised before our eyes, and those who are eager to be on the watch for its appearance and its applications are certainly entitled to have all unnecessary difficulties removed from their path. Of these, so far as research is concerned, one of the most important is its costliness. We have the men, we have the opportunities, and what we chiefly want is to have "the money too."

Annotations.

"Ne quid nimis."

THE HOUSING QUESTION.

IN THE LANCET of Jan. 23rd, p. 248, attention was called to the evidence given at an inquest as to the enormous rent commanded by those who let rooms to the poor in the East-end of London. The difficulties which beset the question of providing the working classes and the poor in London with sufficient and sanitary living accommodation at a price which they can afford to pay are not diminished by the class of tenant which has to be provided for in many instances. The following case, which recently occupied the attention of the Lord Mayor and aldermen at the Mansion House police-court on two successive days, well illustrates this and at the same time shows the high rental exacted by landlords for the rooms in which they allow their tenants to huddle themselves regardless of decency and health. The danger, both physical and moral, to children brought up in such circumstances and the fact that cases of apparently genuine distress are carefully investigated in the City will also be observed. On the first day of inquiry the charge was against a woman named Nowell of exposing her two boys, aged nine years and five years, by causing them to beg in the streets. When arrested she had nine pennies upon her and she pitifully entreated the presiding alderman not to take her children from her and to send them to an industrial school, saying that they went to school regularly already. The police stated that as far as they had then been able to ascertain the husband was a hard-working man who had been out of employment as a dock labourer and who during the past week had only been able to get half a day's work. They added that he and his wife, a daughter aged 19 years, a son aged 17 years, and three children, aged respectively nine years, five years, and two years, lived in a single room in Spitalfields, where they slept on the bare boards and that for this shelter they paid 7*s.* a week rent. With respect to the children, the alderman, who no doubt had experience of such cases, remained obdurate, but while they were remanded for further inquiries and for a school to be found for them, the parents were not forgotten and the Mansion House Unemployed Committee was able to send a police constable at once to the father with the address of a firm where employment would be given to him. On the following day evidence was given that the constable intrusted with the matter called several times at the address of the working man but found no one there, and that the man took no notice of a message left for him informing him of what would be done on his behalf and recommending him to call at the police station. Finally, the constable went to the room in question between 10 and 11 at night when he found the husband drunk and quarrelling with his wife. He gave his message but the man refused to listen to it or to take the address of the firm which would have given him work. At the same time he was abusive, declared that he would drink every halfpenny he had got, and with regard to the proffered employment said that he did not want "any of your —— twopenny-halfpenny jobs." It will easily be understood that while parents of this class can live upon their children's mendicancy, and while those who give alms indiscriminately will assist them to do so, it is difficult to prevent children from being brought up in the midst of disease, starvation, and crime. The housing question is also rendered more complicated where people of this class exist in considerable numbers. They will not go into quarters where decency and reasonably good behaviour with the regular payment of rent are insisted upon and as long as they can find buildings of any kind where they will be tolerated they are content to live there under conditions dangerous to their own health, that of their children, and that of the public. To enforce universal conditions of sanitary life in the case of a huge population, leaving as the only alternative prison or the streets, seems hardly possible, but short of such compulsion it is not easy to see how a healthy and decently behaved people can be obtained or how matters can be prevented from going from bad to worse. Any measures not universally applied tend to increase the congestion in the districts where cleanliness and sanitation are already most needed.

THE POSITION OF WORKHOUSE MEDICAL OFFICERS.

WHILE as the result of concerted action on the part of members of the profession the status of medical men in the navy, army, and Indian services has been improved, the apathy exhibited by Poor-law medical officers has prevented any improvement in their circumstances and has even in some cases been productive of changes for the worse. Triumphant democracy has reversed the old social order and the workhouse medical officer, who has probably some claim to be regarded as a man of culture and education, holds his post at the will of persons with whom he would not in a private capacity care to associate. In a similar way the Local Government Board still insists on including the control of the medical officer among the functions of a master and a matron who are often enough a promoted gate porter and his wife. Our attention has been called to a case in which the right of a medical officer to admit a visitor to a ward nominally in his charge is disputed by the master and matron and however absurd such a condition of affairs may seem it is clear from the orders of the Local Government Board that the right can only be exercised by permission of the officials mentioned. Thus it was laid down, in 1847 be it noted, that one of the duties of that dignified and potent officer the porter is "to keep the gate and to prevent any person not being an officer of the workhouse or of the union, an assistant Poor-law commissioner or any person authorised by law or by the commissioners or guardians from entering into or going out of the house without the leave of the master or matron." The attitude of the Local Government Board towards the hierarchy of the casual ward is shown by a circular letter issued in January, 1895, which runs thus: "The improvement that is taking place in the character of workhouse nursing from the employment of trained nurses occasionally leads to objections being raised to the legitimate exercise of the authority of the master and matron in the arrangements connected with the sick wards. The Board consider that so long as these establishments are constituted as at present the nurses should be responsible to the medical officer for the treatment of the patient, but should clearly understand that in other matters they must defer to the authority of the master and matron" From the views expressed by the recent Departmental Committee on Nursing it would appear that the Board is not now quite so sure of the advisability of leaving a free hand to the master and matron as regards nurses. Perhaps in course of time it may recognise that the medical officer, too, has feelings worthy of consideration.

SCIENCE IN BOYS' SCHOOLS AND MEDICAL EDUCATION.

AT no time probably since the introduction into this country of compulsory school attendance has more general interest been taken in the question of the subjects and methods of education than at the present moment. We have left behind us, we hope for ever, the controversy as to the practical utility and absolute necessity of some form of education for every one of our fellow subjects. We are now entering upon what bids to be even a more prolonged controversy as to the matter and manner of education which shall prove most efficacious in fitting our race to perform its allotted functions. Now that it is recognised that education is for all it is being questioned whether the methods of instruction in the past may not be improved upon. Doubt as to the perfection of our methods extends through every department of learning from the board school to the university. To our shame, but also perhaps to our advantage at the present time, other countries have recognised the need of reform before us and have made experiments in various directions from which if we are wise we may profit. As in medicine so in education, the empirical method is not always the best means of testing efficiency. It is not easy to estimate the influence of all the factors in the environment and because good men are turned out from our public schools it does not follow that the character of the education in those institutions does not need improvement. It is not only by watching the result of different forms of education that we can tell which is the most desirable. Thoughtful consideration of the objects to be attained by education and of the probable results of different measures may often lead to practical reforms, just as researches in the laboratory and the contemplations of philosophical pathologists have often given the clue to effective methods of treating cases which have baffled practical physicians. In trying to ascertain the particular scheme of school education most suitable for an intending student of medicine it is not sufficient even if it were possible to contrast the respective merits of medical practitioners submitted to rival methods of scholastic treatment. Statistics could be put to no more futile use than to estimate the percentage of successes in final medical examinations achieved by candidates educated on the classical and modern sides respectively of our chief public schools. Nevertheless, those who are engaged in medical education must necessarily take the keenest interest in the preliminary instruction of their pupils and they are generally supposed to hold strong views upon the much-vexed question of the rôle of science in school education. The belief that teachers of medicine would naturally desire that their pupils should have studied science at school arises from a false assumption as to the chief objects of a boy's education against which a strong current of opinion is now setting. The tyranny of the examination system is causing a revolt against the view that the acquirement of knowledge is the main object of education. Systems of education dominated by examinations tend to become little else than methods of storing facts in students' brains, since it is the success of this process which is most readily estimated by the examiner. If a teacher of medicine desired his pupil to be handed over to him with his brain well stored with facts upon which subsequent knowledge could be built there is no doubt preference would be given to one who had been instructed in a school in which natural science was fully taught. But teachers of medicine, in common with all those whose duty it is to impart instruction to youths who have completed their school curriculum, find that their best material is characterised not by knowledge but by brain power. The facts which a boy has acquired at school are of little importance compared with the effect that the school training has had upon his intellect and his morals. A boy of high moral sense, well trained to observe and capable of logical reasoning, will make a better medical student though he has never had the least smattering of so-called scientific education than an unobservant boy with an illogical brain stuffed with facts connected with elementary chemistry, physics, and biology. Recognising this fact the medical profession should use its influence to secure that the course of study in preparatory and public schools should be that best suited to develop a boy's senses and intellectual faculties regardless of the subsequent uses to which the facts acquired may be put. Schoolmasters are already too much harried by those whose sole idea of education is that it shall provide useful knowledge. Science is more or less on its trial as a subject of education in schools and it is believed by some to be a very unsuitable subject. It would be unfortunate if the supposed needs of the medical student led to the retention in the school curriculum of a subject which failed to promote intellectual development, inasmuch as the pure science which a medical student requires can easily be provided after school is over. There are some who are disposed to give great credit to the medical profession for such share as it has had in encouraging the establishment of science laboratories in secondary schools. It is a question requiring the most thoughtful and careful consideration whether such laboratories are of real value and in helping to solve this problem the medical profession must not regard the matter from a selfish or utilitarian point of view.

ALBUMINURIA IN THE NEWLY BORN.

IT is well known that the urine passed shortly after birth differs in several details from that passed later, notably in being of low specific gravity, turbid from uric acid and epithelial cells, and of darker colour. Dr. Ssesenowski of St. Petersburg has investigated the urine of infants in the first few days after birth with especial reference to the presence of proteid substances and has recorded his observations in the *Wratschebneja Gazette*, No. 21, 1903. He finds that in the first six days after birth traces of albumin can be detected in 22 per cent. of the cases and traces of mucin in nearly every case. On the first day after birth albumin can be demonstrated in as many as 30 per cent. It is found more frequently where labour has been protracted and is thus more common in first-born children. The less the absolute body-weight of the infant, and the greater the relative diminution of this in the first days of life, the more frequent is the presence of albumin; moreover, its presence appears to depend to some extent upon the temperature of the infant. The presence of mucin is most constant on the first day after birth, when it can be demonstrated in 96 per cent. of the cases. It gradually lessens, so that on the sixth day it can only be found in 50 per cent. Traces of uric acid are found in 60 per cent. and both this substance and albumin are more frequently found when the urine is acid and deeply coloured. Dr. Ssesenowski regards it as incorrect to speak of a "physiological albuminuria" in infants and considers that previous observers have not sufficiently differentiated between albumin and mucin in their investigations. These observations if confirmed are of interest in reference to the frequency of some degree of albuminuria in apparently healthy children and youths, which is estimated by Dr. Clement Dukes to be at least 22 per cent. No explanation is given of this albuminuria in newly born infants, although it is probable that the altered condition of the circulation at birth may be one factor and the altered relations of the skin may possibly be another.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND: LECTURES FOR 1904.

THE Hunterian lectures will be delivered on Feb. 15th, 17th, and 19th, by Mr. T. Crisp English on the After-effects of Head Injuries; on Feb. 22nd, 24th, and 26th, by Dr. Arthur Keith on the Structure and Evolution of the Auricles of the Heart and of a Competent Valvular Mechanism round their great Venous Orifices; on Feb. 29th and March 2nd and 4th, by Mr. L. B. Rawling on Fractures of the Skull, including Mechanism, Pathology, Complications Immediate and Remote, and Treatment; and on March 7th, 9th, and 11th, by Mr. A. W. Mayo Robson on the Surgery of the Pancreas. The Arris and Gale lectures will be delivered on March 14th, by Dr. Percy J. Cammidge on the Physiology and Chemistry of the Pancreas; and on March 16th and 18th, by Mr. J. Herbert Parsons on the Neurology of Vision. The Erasmus Wilson lectures will be delivered on March 21st, 23rd, and 25th, by Mr. E. M. Corner on Acute Infective Gangrenous Processes (Necroses) in the Alimentary Tract. Each of these lectures will be delivered on the respective days at 5 P.M. precisely.

PUBLIC HEALTH IN THE PHILIPPINE ISLANDS.

THE reports of the Board of Health for the Philippine Islands and city of Manila for the months of July and August, 1903, occupy 40 closely printed pages, the introductory portions of each being signed by Dr. E. L. Munson, captain and assistant surgeon in the United States Army, acting commissioner of public health. The first question that is discussed is the number to be assigned as representing the population of Manila. According to a count made by the Board of Health in May, 1901, the number was then 244,732, but according to the first official census under the American occupation, made during 1903, it was 219,941. The decrease in the population of the city since 1901 is attributed to the return to the provinces of persons who had sought security in Manila during and after the late insurrection. This population of 219,941 is classified according to nationality as follows: Americans, 4389; Filipinos, 189,782; Spaniards, 2528; other Europeans, 1117; Chinese, 21,230; and all others, 895. During July there were 346 births and 620 deaths in Manila, giving a general birth-rate and death-rate of 18·52 and 33·21 per 1000 respectively. For the three predominant nationalities the death-rates per 1000 were as follows: Americans, 10·74; Filipinos, 35·32; and Chinese, 22·75. During July there were seven deaths from plague and 38 from cholera. Cholera also became prevalent in three towns lying along the Mariquina river above the intake of the Manila water-supply. The Board of Health therefore sent a corps of medical men, sanitary inspectors, and disinfectors to the Mariquina Valley from Manila, obtained a larger military guard than hitherto for the purpose of quarantining the river, established the pail conservancy system for the reception of human excreta, and organised a corps of scavengers for the collection and proper disposal of the same. By these measures the infection of the Manila water-supply, which at first appeared almost inevitable, was avoided and the disease was stamped out in 30 days. During August the new sea-going steam scavenger barge of the Board of Health was received from the builders. It is of 285 tons burden and is capable of efficiently removing and of dumping at sea the entire excremental waste of the city.

THE EARLY DIAGNOSIS OF ARTERIO-SCLEROSIS.

IN the processes of involution which occur with advancing years the most important and widespread by far is the loss of elasticity of the blood-vessels due to arterio-sclerosis. Accompanying this morbid process there appears a train of symptoms of varying character, generally grave and lasting throughout life. In *American Medicine* of Jan. 2nd Professor Alfred Stengel of the University of Pennsylvania deals with the early symptoms, diagnosis, and treatment of this important affection. Attention has been drawn recently, especially by Clifford Allbutt and von Basch, to the factors which produce premature arterio-sclerosis in many persons. An early recognition of the development of this condition, says Professor Stengel, and a proper regulation of life and habits "may defer the more advanced stages of this malady, if they cannot cause a restitution of previous conditions." When marked arterio-sclerosis of the aorta and large vessels is present the smaller vessels and capillaries have long been affected. From the point of view of diagnosis, therefore, it is important to recognise the involvement of the smaller blood-vessels rather than that of the main trunks. Von Basch, who has given much attention to the subject, suggests that the term "angio-sclerosis" should be used for the widespread and universal affection of the vascular system, while the term "arterio-sclerosis" should be used in a more restricted sense for affection of the peripheral arterial system, and in this opinion Professor Stengel concurs. Starting from the view of Gull and Sutton that, with rare exceptions, the disease begins as a diffuse and general disease of the blood-vessels it is stated by Professor Stengel that the intermediate and later stages show a special local advancement—thus in one instance we meet with a cerebral arterio-sclerosis, in a second with a cardiac affection, and in a third with a renal disorder. The causes that lead to arterio sclerosis have been more common in the United States during the last five decades, a view, adds Professor Stengel, almost uniformly held by physicians of experience. An analysis of the statistical evidence from the census reports of the United States leads to the same conclusion. Among the etiological factors are enumerated continued mental anxiety and exhausting mental work, while the toxic effect of typhoid fever is said to predispose to arterio-sclerosis in later years. Similarly excessive exercise and athletic indulgence may cause changes in the heart muscle and blood-vessels which during the period of robust manhood are of little consequence but which in later life may increase in degree and seriousness, as was pointed out in a leading article in THE LANCET four years ago.[1] Other important causes of arterio-sclerosis are alcoholic intemperance, overfeeding, chronic lead poisoning, and syphilis. "I have seen many cases of advanced arterio-sclerosis," continues Professor Stengel, "in persons who have lived the most correct lives in every respect except overfeeding." A tendency to arterio-sclerosis also exists in some families. In reviewing the early symptoms it is pointed out that the first effects of loss of elasticity in the blood-vessels are an impediment to the easy circulation of the blood and a consequent increase of the work of the heart, with accompanying heightened blood pressure which remains constantly high with occasional remissions. This elevation of blood pressure is found to be an invariable symptom; it is detected by the finger on the pulse or by the use of the manometer of Riva-Rocca or von Basch. Auscultatory prolongation of the first heart sound and a sharp accentuation of the second or aortic sound are present. The earliest subjective or other symptoms which lead the patient to seek medical aid are a failure of vigour, a general feeling of reduced vitality, anæmic pallor, and undue sweating on exertion. "It is active members of the better class, men who have achieved much and suffered much though outwardly successful, that fall early victims to this disease." The easy-going and indolent, adds Professor Stengel, may develop this disease but seldom early except as the result of excesses in eating and drinking. Slight and occasional albuminuria in the early stages of arterio-sclerosis shows that the disease has definitely affected the kidneys but casts are not found in the urine until the disease is considerably advanced. Early cardiac symptoms such as arhythmia, increased force of the cardiac impulse and apex beat, and occasional slight attacks of dyspnœa are frequently encountered. The abuse of tea, coffee, alcohol, and tobacco in such cases is a serious matter, tending to accelerate the progress of the disease. Finally, ophthalmoscopic examination may throw valuable light on the condition. Thus thickening of the retinal arteries and narrowing of the retinal veins have been observed early in the course of this affection in several cases by de Schweinitz.

[1] THE LANCET, Jan. 20th, 1900, p 174.

CANCER RESEARCH AND TEACHING IN BIOLOGY.

Dr. E. F. Bashford, the superintendent of the Cancer Research Fund, has caused to be sent to all British biologists a letter from himself to Mr. A. E. Shipley of the Museums, Cambridge, together with a circular letter in reply from that teacher. Mr. Shipley says:—

> I am told it would very materially assist the work of the Cancer [illegible] f the nature of malignant [illegible] rtebrates, and if it exists, [illegible] caused by nematodes, [illegible] Cancer Resea [illegible] inquiry. Su [illegible] should be pla [illegible] Director, Can [illegible] ment, Londo [illegible] terial from the various [illegible] uld greatly assist the [illegible] ntry if similar supplies [illegible]

The subject of cancer is so important to the medical profession and to the public, while at the same time so little is known of its nature or etiology, that no means of possible information or of investigation should be left untried and we are sure that teachers of biology throughout the country, together with their pupils, will respond heartily to the above appeal.

THE REBUILDING OF ST. BARTHOLOMEW'S HOSPITAL.

ON Jan. 26th a largely attended meeting, of the proceedings at which we give a condensed report in another column, was held at the Mansion House, the Lord Mayor of London being in the chair. The treasurer of the hospital, the Lord Bishop of London, members of the medical and surgical staffs of the hospital, the Chief Rabbi, and representatives of the great mercantile houses of the City all spoke emphasising the necessity for an appeal to the public for funds wherewith to put the ancient foundation into a condition compatible with modern needs. Two motions were carried, the one unanimously and the other with two dissentients, while subscriptions paid or promised were announced to the amount of £40,000. We have already so fully set out in THE LANCET of Dec. 5th, 1903, p. 1587, the reasons why an appeal should be made that there is no need to recapitulate them here. We hope, however, that it will not be long before definite plans for reconstruction are put before the public and that a special appeal will be made to every old St. Bartholomew's man throughout the empire. The sons of the great hospital are working in every quarter of the globe. All can give something, some perhaps only little, others much. Even the price of one brick or one stone will be a help, and if the sons of St. Bartholomew's Hospital do not send their aid others less connected with the foundation cannot be expected to do so. We are sure, however, that the money will be forthcoming and it only remains for all St. Bartholomew's men to remember Sir William Treloar's words that the appeal committee means to prosecute the appeal and it means to get the money.

THE PLURALITY OF DYSENTERY.

WRITING recently under this title in the *Archives de Médecine et de Pharmacie Militaires* Professor Vincent of Val de-Grâce gives a summary of the views which of late years have been advanced regarding the etiology of dysentery. The question, he says, is one of great importance to military medical officers not only from the point of view of treatment but also with regard to prophylaxis. Until the precise nature of an infecting agent is known preventive measures must always be of a more or less empirical description. Quincke and Roos, he continues, have succeeded in differentiating several kinds of amœbæ, some being innocuous or at all events capable of residence in the digestive tube of healthy people without giving rise to reaction, and others pathogenic, possessing the characteristic properties which cause dysentery. In addition to the non-pathogenic amœba intestinalis vulgaris these writers recognise an amœba coli mitis and an amœba dysenteriæ, the last named being smaller than the other as well as more mobile and also inclosing red globules. The amœba coli mitis contains only bacteria and is pathogenic in man alone. The amœba dysenteriæ is pathogenic in man and also in the cat and possibly in the dog. Summing up, Professor Vincent comes to the conclusion that dysentery is complex; it is the common expression of several infections of a different nature. As a matter of fact the human organism when in conflict with pathogenic agents is not in possession of an unlimited number of modes of reaction. If the lesions caused by the bacillus of Shiga and by the amœba of Loesch are sufficiently different the symptoms by means of which the mucous membrane of the large intestine makes known its suffering are identical in the two affections. It seems as though the etiological unity of dysentery dogma, which a few years ago no one would have dreamt of contesting, was about to vanish. There are various kinds of dysentery, just as there are various kinds of broncho-pneumonia. Each kind of dysentery has, it may be, its special capabilities for epidemic transmission. That is what future investigations will teach us. In connexion with the plurality or not of dysenteric poison attention may be drawn to a thesis entitled "Les Dysenteries, Étude Critique" by Mlle. Broïdo, a Parisian student who is now medical officer on board a passenger steamer belonging to one of the great French lines. In this work Mlle. Broïdo treats of the pathogenic complexity of dysentery and summarises the actual state of the question. She recognises an amœbic form of the disease and also a bacillary form. In a group still requiring investigation she includes (1) dysentery due to the balantidium coli; (2) dysentery due to the bacilli of Ogata; (3) dysentery due to the bacilli of Roger; (4) dysentery due to the cocco-bacillus of Lesage;

and (5) finally dysentery due to the various pseudo-dysenteric bacilli. Mlle. Breido does not think that true dysentery can be caused by non-specific microbes.

A PRAISEWORTHY FAD.

POPULAR crazes in matters of medicine and of hygiene are more often than not things to be deplored. If they are not actually harmful they are generally ridiculous, and if they are of no benefit to the general public assuredly they are, as a rule, of equally little advantage to the medical profession. The net result is most often a fine haul for a few quacks and loss and disappointment for a large number of "patients." It is with considerable complacency therefore that we may view what seems almost to amount to a "craze" at the present time. We allude to the prevalent exploitation of eating slowly and eating less. A more generally beneficial doctrine could hardly be chosen for the popular medical idol of the moment. A lay contemporary has recently devoted many paragraphs to the researches and experiences of an American gentleman, Mr. Horace Fletcher, who has made it the business of his life to demonstrate that most people eat too much and eat too fast. Incidentally he believes that a new throat reflex has been discovered insuring proper mastication for the "slow feeder." Mr. Fletcher's results have interested physiologists and many of his experiments were carried on at Cambridge in association with Sir Michael Foster and other physiologists at that place. As an enthusiast Mr. Fletcher sees in the reduction of the quantity of food necessary for the individual far-reaching results, amongst others the kernel of national military success by the simplification of the commissariat problem. Napoleon's dictum that an army "moves on its belly" is to be altered and the instructed army will hardly need a belly to move on. Whatever may be the wide effects of the adoption of such a system of feeding as Mr. Fletcher proposes, at any rate there can be no question of the individual advantage that would follow in most cases from such a course. A similar lesson, in a less convincing form, is, of course, the central point of the mysterious successes that attend Mr. Barrie's heroine in his play of *Little Mary*, and if when lay writers deal with medical subjects they were always to work in such directions the medical profession would welcome them as valuable coöperators, as, indeed, we do in the case of Mr. Horace Fletcher.

POOR-LAW MEDICAL OFFICERS IN THE HIGHLANDS AND ISLANDS OF SCOTLAND.

THE Scottish Poor Law Medical Officers' Association, which is a body formed for the purpose of looking after the interests of a hard worked and very poorly paid body of men, has just issued its report for 1903. To Mr. J. Cathcart Wason, Member of Parliament for Orkney and Shetland, was intrusted the responsible task of introducing in Parliament a Bill promoted by the association. He was, however, unable to do so during the last session. The report further states that owing to the advertisements of the association which have appeared in the medical press applicants for vacant Highland and island appointments have applied to the secretary of the association for information with the result that the inquirers ceased to be applicants for the posts. The committee hopes this year to advertise also in the *Scotsman* and the *Glasgow Herald*. Particulars are then given of various parishes which have been without medical officers during the greater part of the past year. The report ends with an appeal to all Poor-law medical officers in Scotland to join the association and this appeal we cordially endorse. We are always glad to do what lies in our power to assist a Scottish Poor-law medical officer to obtain the advantages for which we have always contended—namely, fixity of tenure, adequate salary, a free official residence, and a free annual holiday—i.e., with payment by the parish council of a locum-tenent. But we cannot help those who will not help themselves and we learn from the report that although there are 850 Poor-law medical officers in Scotland only 350 nominally belong to the association and of these many omit to pay their subscriptions. This, as the report goes on to say, is not fair.

THE PREVENTION OF LEPROSY.

OUR readers have probably read the correspondence which has occasionally appeared in the *Times* on the causation and prevention of leprosy. A long letter was recently published from Mr. Jonathan Hutchinson who once more explains in considerable detail his theory that leprosy is due in the main to the consumption as food of decomposing or imperfectly cured fish. This theory has received some support, editorially and otherwise, in the columns of our contemporary. Mr Hutchinson admits that the fish hypothesis has not as yet been openly endorsed by many of the leading members of the medical profession and we have throughout maintained that his theory has not yet been proved. His views, however, can only be received with respect and the hope expressed that further investigations will be forthcoming which will corroborate or otherwise the conclusions at which he has arrived after the most painstaking efforts to discover the truth. If he is correct in the etiology of the disease his remarks on its prevention should receive world-wide attention.

THE BRITISH DENTAL ASSOCIATION.

AN extraordinary general meeting of the British Dental Association was held on Jan. 23rd at the Examination Hall, Victoria Embankment, London, to consider the question of the expediency of a degree in dentistry. A motion was proposed by Mr. J. H. Badcock and seconded by Mr. L. Matheson :—

> That a memorial be presented to the Senate of the University of London praying for the institution, in the interests of dental science, the public, and the dental profession, of a degree in dental surgery in the Faculty of Medicine, but expressing the further opinion that it would be undesirable to make the possession of the M.B., B.S. degrees a necessary qualification for such a degree.

An amendment was proposed by Mr. David Hepburn and seconded by Mr. Montagu F. Hopson :—

> That the creation of d[illegible] desirable and that the opinion of this meeti[illegible] consider the expediency of a degree in [illegible] to the universit[illegible] of the United Kingdom.

A vigorous discussion ensued and the amendment was carried by a large majority.

RINGWORM AND THE METROPOLITAN ASYLUMS BOARD.

AT a meeting of the Metropolitan Asylums Board on Jan. 23rd the children's committee reported that at the Downs Ringworm Schools during the year ending Dec. 31st, 1903, 618 children were admitted, 208 were discharged, and one had died. Of the discharges, 153 were pronounced cured, 14 were transferred to the Bridge School or elsewhere, and 41 were sent for by the guardians. The committee stated that it regretted to observe that so large a number of children were removed from the schools before they were cured of the disease, thus tending to defeat one object for which these schools were intended. Although the committee was not prepared to indicate a remedy it thought that some action should be taken and therefore recommended that the facts should be reported to the Local Government Board and that it should be asked to favour the managers with an expression of its views thereon. The report and the recommendation were adopted.

THE DEATH OF WHITAKER WRIGHT.

When it was first learnt that Whitaker Wright, found guilty upon all counts of the indictment against him and sentenced to seven years' penal servitude, lay dead within the precincts of the court in which he had been tried, suicide seemed so probable and appropriate an ending to his career that it must at once have suggested itself to the minds of all. A story more or less circumstantial of sudden heart failure followed and seemed to the lay mind little less likely to be true when those who heard it considered the physical and mental strain to which the man had been subjected. Medical men, however, failed to recognise in the events of his last moments much probability of death having occurred either from heart failure or cerebral hæmorrhage. It is now known that it was by his own act that he obtained release from the sentence which his reckless pursuit of wealth *per fas atque per nefas* had brought upon him, and that the confidence with which he had vaunted his innocence had been accompanied by the doubt lest a jury of his fellow men might hold other views. Comment was recently made in THE LANCET upon a Home Office circular as to the prevention of suicide by prisoners admitted to bail, and it was pointed out how rarely suicide is attempted by men who have violated the law and have been brought to book for their misdeeds. Whitaker Wright, however, was an exceptional man, and apart from any misgiving which he may have felt latterly as to his position in the eye of the law it is doubtful whether at any time he acknowledged even to himself that he had committed any moral wrong. Such a man would never have been able to reconcile himself to enduring a sentence, the justice of which a weaker criminal would have inwardly admitted. He has preferred, on the other hand, to pay the penalty which the law of all civilised nations regards as the heaviest that can be imposed.

LECTURES AT THE HOSPITAL FOR CONSUMPTION, BROMPTON.

The lectures and demonstrations given by the members of the visiting staff of the Hospital for Consumption and Diseases of the Chest, Brompton, have now recommenced, the first lecture having been delivered by Sir R. Douglas Powell on Jan. 27th. These lectures are held on Wednesdays, at 4 P.M., and are free to all qualified medical practitioners and to students of medicine The attendances at the lectures which were given in the first part of the winter course fully prove the real value attached to them by those for whom they are intended. The wealth of clinical material available at the hospital is immense; numerous cases are demonstrated at each lecture, so that those who are present are enabled to obtain the benefits conferred by actual examination of the patients. The next lecture will be given by Dr. J. Kingston Fowler on Feb. 3rd, the subject being "The Treatment of Thoracic Aneurysm by Gelatin Injections." The course will be continued until March 16th

The medical officer of health of the Cape Colony reports that for the week ending Jan. 2nd only one case of plague was reported throughout the colony—namely, that of a native child at East London. Plague infected rats were found at Port Elizabeth and at East London, but of 205 rats examined during the week within the Cape Town and Harbour Board area none was affected with plague. As regards the Mauritius a telegram from the Acting Governor (received at the Colonial Office on Jan. 23rd) states that for the week ending Jan. 21st there were 16 cases of plague and 12 deaths from the disease.

The Swiney Prize, founded by Dr. Swiney, who died in 1844, for a work on jurisprudence, has just been awarded to Sir Frederick Pollock, Bart., LL.D., D.C.L., and Professor Frederic William Maitland, LL.D., D.C.L., for their book on "The History of English Law before Edward the First." The prize consists of a silver cup of the value of £100 and money to the same amount. The award is made jointly by the Society of Arts and the Royal College of Physicians of London and the prize, under the terms of Dr. Swiney's will, is given every fifth year on the anniversary of the testator's death.

The Lettsomian lectures of the Medical Society of London will be delivered by Mr. C. B. Lockwood at the rooms of the society, 11, Chandos street, Cavendish-square, W., on Thursday evenings, the 1st, the 15th, and the 29th of February, at 9 P.M. Mr. Lockwood has taken as his subject, Aseptic Surgery in Theory and Practice, and will deal among other things with the choice and use of antiseptics and with the comparative results of operations in private houses, nursing homes, and hospitals.

At the opening of the fourteenth session of the London School of Tropical Medicine, which commenced on Jan. 15th, 28 students entered for the three months' course. Of these two are women. Seven students belong to the Colonial Office service and three to missionary societies Four students entered for a period of study less than three months.

As our readers know, an important meeting of Oxford graduates was held early in the year to consider the appointment of a successor to Sir John Burdon-Sanderson, as Regius Professor of Medicine in the University. We understand that at present His Majesty's advisers have made no recommendation to the post.

We are informed that His Majesty the King has consented to open the new University buildings at Cambridge early in March.

Medical Prizes of the Paris Academy of Sciences.—The *Revue Scientifique* of Jan. 16th publishes a list of prizes, the award of which will be decided by the Paris Academy of Sciences during 1904 and several subsequent years up to 1913 The value of individual prizes varies from 200 francs (£8) to 100,000 francs (£4000). The following are those connected with medicine or the medical sciences and having a value of 2000 francs or upwards. Prix Montyon: three prizes of 2500 francs for discoveries in therapeutics and improvements in medicine and surgery. Prix Barbier: prize of 2000 francs for a valuable discovery in medicine, surgery, pharmacy, or medical botany. Prix Bréant: prize of 100,000 francs for a discovery relating to the cure, etiology, or prophylaxis of Asiatic cholera. Prix Mège. prize of 10,000 francs for the continuation and completion of the work (*essai*) of M. Mège on the causes which have hindered or promoted the progress of medicine. Prix Leconte. prize of 50,000 francs for new and important discoveries in mathematics, physics, chemistry, natural history, and medical sciences. Prix Serres: prize of 7500 francs for the best work on embryology, applied as much as possible to physiology and medicine. Prix Dusgate: prize of 2500 francs for the best work on the diagnostic signs of death and on the prevention of premature burial. Prix Parkin. prize of 3400 francs for researches on the curative effects of carbon in its various forms, and particularly in the gaseous form in the treatment of cholera, fevers, and other diseases. Prix Chaussier: prize of 10 000 francs for the best work on legal medicine or practical medicine which has appeared for four years. Prix Lacaze: prize of 10,000 francs for works or memoirs which have advanced physiology.

OSBORNE HOUSE CONVALESCENT HOME

FOR OFFICERS OF THE NAVY AND THE ARMY.

THE KING'S GIFT TO THE NATION.

(BY OUR SPECIAL SANITARY COMMISSIONER.)

THE fact that there was no convalescent home for the officers of the navy or the army is an omission that made itself keenly felt during the South African war. Even abroad, notably Costabelle on the French Riviera, hotel keepers were offering to receive as guests or on special terms convalescent British officers, but at home neither the Admiralty nor the War Office was able to give such facilities. The convalescents therefore came to London or went to stay with friends and many doubtless suffered owing to want of a home which, though not actually a hospital, nevertheless was capable of affording all the means of continuing whatever treatment might be required. There are, of course, many convalescent homes but these are for the most part either charitable or semi-charitable institutions, or else they are commercial undertakings where the charges made are often the reverse of moderate. It was therefore a difficult matter to know what to do with officers who were discharged from the military hospitals but who were not yet fully restored to health. The necessity of convalescent homes is so widely recognised that these are provided for all classes of the community. At Birmingham and in other towns the working classes levy among themselves several thousand pounds every year so as to maintain convalescent homes of their own in the country, at the seaside, or among the Welsh mountains. In spite of the help which it might be thought would be forthcoming from the War Office and the Admiralty, that which working men, without any State aid, have done for themselves had never been attempted on behalf of the officers of the navy and the army. In the midst of the trouble which this negligence occasioned Her Majesty Queen Victoria died and on succeeding to the throne King Edward VII. naturally felt desirous of commemorating his mother's memory by some notable deed. It then occurred to the King that this purpose would be achieved in a useful and practical manner if he gave the wherewithal to found the much-needed convalescent home for officers of the navy and the army. Such a home might have been provided at a comparatively small cost on any suitable site but then it would not be connected with the late Queen and the present sovereign in a sufficiently emphatic manner. Therefore His Majesty determined to make a present to the nation of Osborne House and the surrounding magnificent estate. For this purpose a special Act of Parliament was passed entitled "The Osborne Estate Act," or 2 Edward VII., c. 37. In this it is related that the Osborne estate was left by the late Queen to His Majesty for life, but that with the approval of the Prince of Wales the King had expressed his desire that on the occasion of his Coronation the Osborne estate should be made over and become a part of the public property of the Sovereign. Further, it was enacted that provision should be made so that the house and gardens might be used as a memorial to the late Queen. Only a certain small portion of the estate was reserved for the private use of members of the Royal family. Osborne House and the adjacent grounds were therefore placed under the management of the Commissioners of Works and the rest of the estate under the Commissioners of Woods. The Act further directs that :—

> As a memorial to Her late Majesty the Commissioners of Works—*(a)* shall, during His Majesty's pleasure, preserve, so far as may be in its present condition, and keep open to the public in such manner and on such terms as the Commissioners, with the approval of His Majesty, determine, such part of Osborne House as appears to have been in the personal occupation of Her late Majesty; and *(b)* shall devote the rest of Osborne House and the grounds under their management to be used for the benefit of officers of His Majesty's naval and military forces or their wives, widows, or family.

Here then were a vast building and estate placed at the disposal of the nation and the chief concern was that of making the best use of this Royal largess. A part of Osborne House could be preserved as a sort of museum where visitors might see the Victorian style of decoration. This consists of the council chamber, the dining room, drawing room, and the Durbar Room, together with other apartments which were constantly used by the late Queen. The greater part of the building, however, consisting of the rooms and apartments utilised for the Royal suite and visitors, would afford no special interest to the public and it was proposed that it should be so altered as to be available for the purposes of a convalescent home.

There still remained close at hand the stables and the cricket grounds and it was felt that others besides the convalescents should profit by this vast estate. It was therefore determined to create on this spot a naval college. With great promptitude a series of elegant pavilions have been constructed which already contain 198 cadets of the Royal Naval College and eventually there will be accommodation for a total of 375 cadets. These buildings have been erected by the Office of Works at the expense of the Admiralty. It will help to build up the health and strength of these young pupils to give them the run of this fine estate. The same, it is to be hoped, will be the effect of the situation on the convalescents who will live close by at Osborne House. The site of this building is admirable. It is on the highest elevation of the neighbourhood and is swept by the sea air from all sides. At Osborne House a commanding view of the sea can be obtained and the grounds extend to the shore where there are a beach and a sea wall within the estate. That the climate is exceptional is shown by the vegetation, for, among other trees, the cork oak flourishes here and in an extraordinary manner and early in January I found some Mediterranean heather in full bloom.

Those who know Osborne House will remember that the main building forms three sides of a square to which, however, several wings and out-buildings have been added from time to time (Fig. 1). Facing the main entrance there are on the left the apartments of the late Queen and the Durbar Room, which on certain days will be open to the public. These are sufficiently separated by a broad court from the right-hand side portion of the building where the convalescent home will be established. This part of the building is well suited for the purpose. There are three floors and two wings. The end of these wings communicates, on one side, with a passage and parallel with the passage is a terrace or colonnade that overlooks the main yard or court of the principal entrance to Osborne House. On the third floor these wings communicate with an open terrace formed by the roof of the sheltered colonnade which corresponds with the second floor. Thus without leaving the building or descending the stairs the patients can be wheeled out or can walk out into the open air. On the second floor the open air can be enjoyed when it is raining, for the colonnade is very broad and affords ample shelter (Fig. 2). This is a convenience that will not fail to be of special service to the patients. As for the rooms, it has been necessary to make very extensive alterations. Some rooms were too large and others were too small so that the position of the partition walls had to be changed. Then the paper from the walls had to be removed, together with some useless and dust absorbing ornamentation. The walls are now treated with velour paint that can be washed and kept thoroughly clean. Light pleasant colours have been selected: a soft green for the third floor, light blue for the second, and strawberry and cream for the first floor. While the walls and size of the rooms were thus modified, all the old-fashioned and extravagant smoke-producing and coal-wasting grates were removed and Tropican grates were substituted throughout. Moreover, all the closets had to be reconstructed, every soil-pipe removed and replaced, and the entire drainage system planned anew and re-laid. In connexion with this bathrooms had also to be provided and there are now four bathrooms on each floor. An iron staircase has been built at the extremity and outside each wing so as to provide a means of escape in case of fire. At the other extremity of the wings there are the terrace and the colonnade gallery. But over and above these precautions there is a huge tank at the top of the kitchen stairs provided with a fire hose and this will supply a full flow of water for 15 minutes. In that period of time the stationary steam fire engine can be made to work and would throw water over the whole building. Each room is provided with a telephone suspended near to the bed and a night emergency bell.

The furniture has been especially devised by Mr. Bailey of the Office of Works with the advice of Miss McCaul,

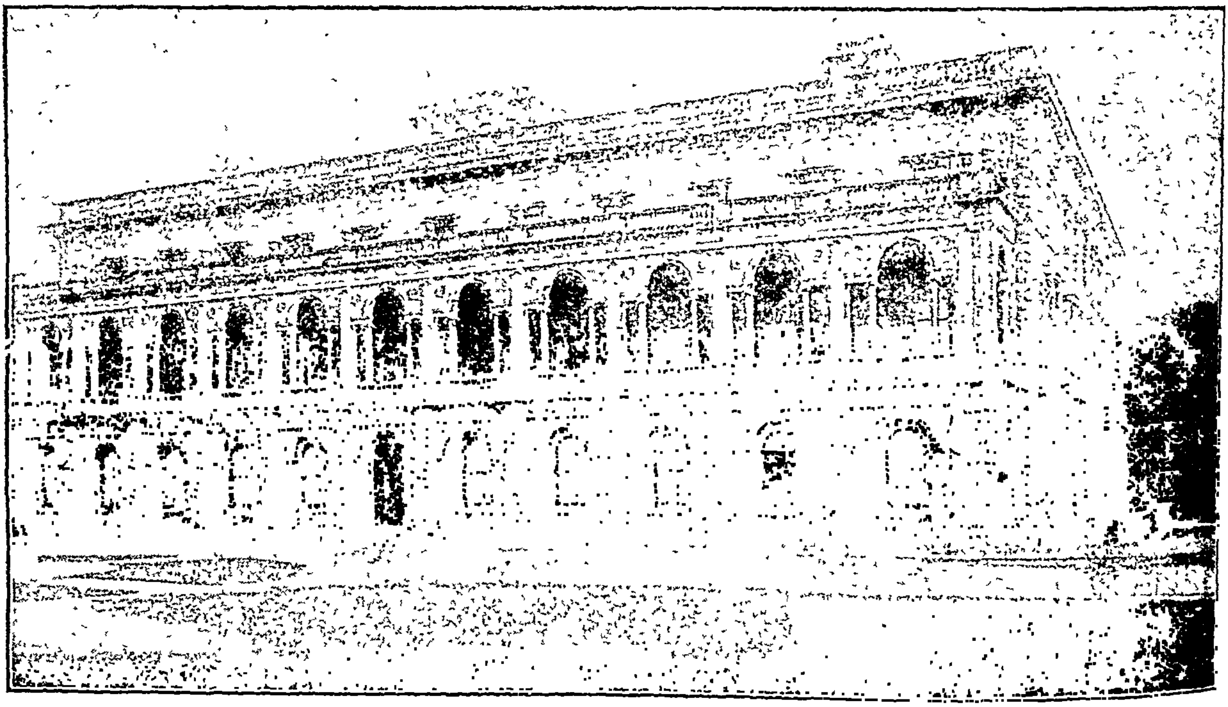
R R.C., so as to be as aseptic as possible. Vare's enamel white paint is used throughout. This has been carefully analysed and contains no lead whatever. The furniture is enamelled inside, outside, and underneath so that the absorbent pores of the wood are closed everywhere and washable surfaces exist on all sides. No angles are allowed; all is rounded off inside the chests of drawers, the wardrobes, &c., as well as outside. For the night tables the back has only bars of wood, the door in front having an open space at the top so that the air passes through freely. This furniture is really remarkable. It is none the less elegant and cheerful in appearance because all these sanitary precautions have been taken in its construction. Something similar should be used in hotels and other much frequented places. The Victoria hall has been converted into a smoking and music room. There are here an organ and a library. There will also be a piano but the room is well away from the rest of the building so that the noise or music will not disturb the patients in their bedrooms. In summer the windows on the sunny side can be closed and shaded, while the door-windows on the other side open out on to the terraced gardens which will be preserved for the private use of the patients. These beautiful terraces constitute one of the most charming features of the estate and will be a great boon to the enfeebled who need some brightness, fresh air, and a little exercise within immediate proximity of their rooms. Near at hand there is a drawing room reserved especially for ladies. In the other wing there are a billiard room and a large and a small dining room. This wing does not overlook the sea or open on to the terraced gardens but it faces the south, receives the sun's rays, and gives access to the park with its splendid trees.

Fig. 2.



View of the building showing the verandah and the open promenade on the second floor.

The general impression is that of vastness—a large palatial building; lengthy, broad corridors; lofty rooms, many of them much larger than necessary. Then there is the grand stretch of park and sea, of lawn and shrubberies, with majestic trees that stand like an army round this Royal retreat to break the force of hostile winds and to provide friendly shade and protection. Among all this foliage and the numerous evergreens there is a great variety of birds, while below almost any plant will grow. Thus the naturalist will find much to interest him and this may help many to pass time agreeably in the open air. The one objection is due to the too frequent rains and the consequent dampness and mist. But here again there is the advantage that Osborne House was built with extraordinarily thick and solid walls, so that it can well cope with these climatic disadvantages. Also, being situated on an elevation the air is bracing, and for those who can take exercise further healthy relaxation may be obtained on the neighbouring golf course, while there are 28 miles of good road for cycling.

The accommodation which the convalescent home at Osborne will afford is to be divided as evenly as circumstances permit between the navy and the army. There will be 38 rooms for single convalescents and five sets of two rooms or room and dressing room for married couples. Further, there is a spare bedroom where a near relative of any of the patients might stay as a visitor in a case of emergency. For admission the officers must be recommended by the Director-General of the Medical Department of the Royal Navy, subject to the approval of the First Lord of the Admiralty, and by the Director-General of the Army Medical Service, subject to the approval of the Secretary of State for War. Commander Powell, R.N., has been appointed house governor and will reside on the estate. The inmates of Osborne House will be provided with fuel, light (electric), and attendance, food, and such stimulants as the medical officer may consider to be absolutely necessary for the treatment of the case and shall order. A stoppage of 2*s*. 6*d*. a day will be made for single men and 5*s*. for married couples. No children, officer's servants, or dogs will be allowed. Efficient service will be provided and there will be a staff of trained nurses. But there is a rule that no gratuity shall be given to any person employed at Osborne House under the penalty of dismissal, so that the only expense incurred will be the payment of 2*s* 6*d*. a day. Yet breakfast, lunch, afternoon tea, and late dinner will be provided, together with medical attendance, such special invalid food and medicaments as may be needed, baths, and ample opportunity for outdoor exercise and whatever relaxation may be pleasant provided that it is not injurious.

There can be no doubt that King Edward VII. has earned the gratitude of his subjects by his kind and timely action By establishing the Osborne Convalescent Home for officers of his navy and army he has also provided a monument in honour of his late beloved and gracious Mother which is in entire consonance with the traditions of her long and beneficent life and reign.

SOME POINTS CONCERNING NATURAL MINERAL WATERS IN GENERAL AND APOLLINARIS WATER IN PARTICULAR.

WE have before discussed the question of the therapeutic superiority of natural mineral waters compared with those artificially prepared. The results of quite recent investigations, the discovery of the fact that the Bath and Buxton thermal waters, for example, are radio active, may possibly lead to a more satisfactory explanation of the favourable action of natural mineral waters in hydrotherapy. In previous articles[1] upon the subject attention was drawn to the fact that the effects of the salts in natural mineral waters are such as cannot be obtained from any artificial imitation of them. Possibly the fact that a natural water containing certain salts in certain proportions acts more favourably than does a water to which salts in the same pro-p[illegible] be accounted for in s[illegible]perty, radio-activity, v[illegible]y all natural waters in a more or less degree. On the other hand, it has been surmised that natural waters contain mere traces of many salts which are not present at all in artificial waters and which may possibly exert important beneficial effects upon the body. There is, again, the question of the formation under immense pressure in natural waters of double salts which have a different effect from that of the salts taken separately, their absorption in the single condition being less certain than when in the coupled state. Thus it has been shown that when a natural water was given more mineral matter was absorbed in a definite time by the intestine of a dog than was the case when artificial water of the same composition was similarly exhibited. Whatever may be the correct explanation, the fact that natural mineral waters act more favourably than do the artificial preparations is of decided importance and the discovery of a means of differentiating the one from the other would be a gain to medical science.

For some time past sinister suggestions have been made as to the origin of certain so-called natural table mineral waters imported into this country and in particular in regard to one of the best known—viz., Apollinaris water. Laymen and medical men alike, if they have not shared the view, have often heard it expressed that the Apollinaris spring was a mythical entity and that the water sold in this country was a manufactured article. This suspicion developed until it culminated in a very definite action being taken by a certain section of the mineral water trade some months ago in the fo[illegible]ompany wi[illegible] selling its [illegible] and the proceedings were watched by many eager to know the truth about Apollinaris water. The false description which was complained of was said to be contained upon the label which appears upon the bottle describing the water as "Apollinaris natural mineral water," with a picture of the spring bubbling up, and the representation contained thereon that the water was a natural mineral water. Evidence was given purporting to show that so far from Apollinaris (in bottle) being a natural mineral water bottled as it comes from the spring it was, in fact, to all intents and purposes, an artificial manufactured article. In support of these statements the processes of manufacture necessary for the bottling of the water and its preparation for sale to the public were described. In the end the magistrate decided that the prosecution must fail and he thought that it would be wholly misleading to class this product among artificial mineral waters. The summons was therefore dismissed and the case was afterwards taken to the High Court of Justice, with the result that the Lord Chief Justice said that it was quite impossible to interfere with the judgment of the magistrate. "I understand," his lordship observed, "that the water and the [illegible] gas is the same [illegible], it is drawn up [illegible]

It is of interest to inquire into the facts upon which so important and definite a conclusion was based. The evidence purporting to show that, so far from Apollinaris water being a natural mineral water bottled as it comes from the spring, it is in fact to all intents and purposes an artificial manufactured article, was based on the following brief account given by counsel as to the processes adopted at the Apollinaris spring for the bottling of the water before its exportation and sale to the consumer: (1) the pumping of water into open tanks in which, after the addition of a small quantity of salt, it was left exposed to the air in order to precipitate the trifling quantity of iron in the water; (2) the addition subsequently of carbonic acid gas obtained in the neighbourhood of the spring; and (3) the bottling of the water under a pressure equal to three or four atmospheres of this carbonic acid gas.

That is a brief statement of the case which, however, necessarily omits certain important details that if not taken into consideration might lead to an erroneous inference. This statement omits certain particulars as to those important steps in regard to the preparation of the water for sale which have given rise to considerable contention—steps which if not observed would put an end altogether to the supply of bottled natural aerated mineral water to the public from any naturally effervescent spring. The actual position can, in a word, only be appreciated by making a personal inspection of the spring and of the processes of bottling, and by submitting samples taken at various points to perfectly independent analysis. We have considered it of interest, bearing in mind the scepticism which has existed, to institute such an independent inquiry ourselves. We therefore instructed one of our Special Commissioners to visit the spring (and it may at once be said that the spring is at all times open to the inspection of any medical man who cares to visit it himself; moreover, a public highway intersects the property), to describe all he saw, to take samples where and whenever he considered expedient and germane to the aim of the inquiry, and subsequently to submit these samples to analysis and to compare the results so obtained with the analyses of samples of the water purchased in the open market. It may be stated that the company not only gave our Commissioner permission to visit the springs and to enter the bottling sheds and every place connected therewith when he chose, but afforded also every facility in order that the inquiry might be made as complete as possible.

The Apollinaris spring is situated in the valley of the river Ahr which flows into the Rhine on the left bank about midway between Bonn and Coblentz. The Ahr valley bears signs of past volcanic disturbances and there are several springs in its vicinity which are not only gaseous but thermal. Neuenahr, close to the Apollinaris spring, is a rapidly rising health resort, with a very complete equipment of appliances available for modern balneological practice. There are also the usual provisions for the accommodation of visitors at a watering place—hotels, winter gardens, concert-room, pump-room, &c. The railway to Neuenahr leaves the main line on the left bank of the Rhine at Remagen, close by the Apollinaris Kirche. The distance is about six miles from Remagen. Beyond Neuenahr is a very beautiful valley up to Altenahr by way of Ahrweiler and Walporzheim, both the railway and road passing through a very fertile vine district and very good wine is produced there. The Apollinaris spring itself is situated in the midst of vines, and, indeed, its discovery in 1851 was due to the observation that in a certain spot of the vineyard the vines refused to grow and died, and a black patch resulted which proved to be due to the escape of large quantities of carbonic acid gas from the earth. Upon excavating the earth eventually a spring was found giving off gas and it is this spring which has yielded ever since a plentiful supply of gas and water both of entirely natural origin sufficient to keep pace with the enormous demand that the popularity of Apollinaris water has entailed.

It is a remarkable fact that in spite of the enormous drain to the extent of 30 million bottles per annum upon this spring it shows no signs of being exhausted. Our Commissioner was able to observe the effect of the level of the spring when very large volumes of the spring water were being bottled. Any perceptible lowering of the level by an excessive demand is rapidly compensated and the yield of gas is far in excess of the requirements. The spring cannot be approached without first thoroughly ventilating the space within the walls which surround it. As the steps to the spring are descended a curious sensation of warmth is experienced, first by the feet, then by the legs, until it is not wise to descend lower into the lake of heavy gas. The smoke from an extinguished match floats upon the gas, the depth of which is several feet. By slowly lowering a lighted match the exact level of the gas lying over the spring can be ascertained by the flame being suddenly extinguished. The actual source of the water is unknown and can only be a matter of speculation; suffice it to say that it is quite warm and in cold weather clouds of vapour arise from it. The actual temperature proved to be 20° C. Apollinaris water may thus be classed as a thermal water. The water is drawn at a depth of 50 feet from the surface and the gas is collected at the top in a large bell-jar on the same principle as that of a gas-holder at the gas-works but on a smaller scale. On its way to the tanks the water receives a slight addition of common salt. What this addition amounts to in practice will be found from a consideration of the results of analyses made in THE LANCET Laboratory of the water taken directly from the spring and of the water after it has received this addition.

---

[1] THE LANCET, July 12th, 1902, p. 94; Dec. 5th, 1896, p. 1622; August 8th, 1891, p. 307.

The water, which is perceptibly warm, is next run into tanks of which there is a great number. Here it is allowed to be at rest for several days, generally a week. On its introduction into the tanks the water cools and by unavoidable contact with the air absorbs oxygen; a small portion of the iron normally present in the water is oxidised into hydrated oxide of iron which separates in the form of a fine rust-coloured sediment. At the same time a slight film of carbonate of lime forms on the surface. The tanks are covered with screens to keep out dust. At the end of seven days the water is ready for re-uniting with the gas from which, to a considerable extent, it parted company deep down in the spring. It is drawn off perfectly clear and bright and pumped into the carbonators which are heavily lined with the purest block tin. Pure block tin, it may be remarked, is the only metal with which Apollinaris is ever allowed to come into contact during the bottling process. In the carbonators the water and the gas are blended and the partnership which existed between them in the spring is thus re-established. The gas is pumped directly from the spring into vertical cylinders where it is kept at a pressure of about three or four atmospheres. The carbonators are provided with paddles which beat up the gas and water. After carbonation is complete the water with its three or four atmospheres of gas passes to the bottling machines. The gas is so pure in its natural state that it undergoes no treatment whatever; purification would be superfluous and this is borne out by the results given on analysis. At intervals the gas previously to being discharged into the carbonators is tested and a record is carefully kept of the results which show that the proportion of carbonic acid gas is on an average within a few tenths of 100 per cent. The composition of the gas is remarkably constant. Similarly the gas given off by a bottle of the water taken directly from the bottling machines is regularly tested as to the proportion of CO_2 Here again the percentage of pure carbonic acid gas is only short of 100 by a few tenths which consist in the main of air which it is impossible to eliminate entirely during the bottling process. Air adheres to the walls of the bottle in spite of the care taken to remove it by sweeping it out with gas before filling with water. Corking, wiring, capsuling, and labeling complete the process and there is little more to be described. The bottling sheds are very large and the bustle and noise within them at a busy time are considerable. There are some 700 hands employed there.

On several occasions when our Commissioner visited these sheds the quantity of water being bottled was equal to 90,000 bottles per diem. In the summer this daily quantity is doubled. The utmost care is taken to preserve the cleanliness of the water; the corks and bottles are scrupulously cleansed and submitted to several processes before they are consigned to the filler and every bottle is carefully examined in a very strong light before it is ready for labeling and packing. Similarly, care is taken with the stone jugs before being filled with Apollinaris water; the operation of filling and corking the stone jugs is slightly varied owing to the opaqueness of the stoneware. The jugs are completely filled with the water under pressure and then a wooden plug is inserted which displaces a volume of water sufficient to allow room for the cork and a little more besides for the expansion of the water. Necessarily some gas is lost during this process. As a rule the water keeps cooler in the stone jugs and is largely protected from the influence of light and heat.

So far the following important facts have been ascertained in regard to the bottling of Apollinaris water: (1) the water of the spring itself is bottled; (2) the gas is the natural gas of the spring; and (3) the supply both of gas and of water is abundant and in spite of the enormous number of bottles filled day by day there is no evidence of this supply diminishing. As a matter of fact, the natural supply of both water and gas is considerably in advance of present demands.

We may next consider the steps which are employed in connexion with the bottling of the water and which are deemed necessary in order that the water may reach the consumer in a satisfactory condition. The mineral ingredients of Apollinaris may be taken to be the same in nature and amount whether the water is drawn deep down or just below the surface. The amount of carbonic acid gas dissolved in the water, however, will obviously vary according to the depth from which it is taken, or, in other words, to the pressure. That there is a superabundance of gas in the spring is patent from the enormous volume that escapes at the surface. This disengagement of gas at the surface merely means release of pressure, so that while the water at the top would only contain its own volume of gas (the point of saturation at the atmospheric pressure) that down below would contain as many more volumes according to the increased depth. In fact, a pint of Apollinaris water drawn from near the surface contains, we found, barely a pint of gas, but the volume of dissolved gas increases as the columnal pressure is greater until about 50 feet down the pressure is equal to two and a half atmospheres. This has been ascertained by experiment in which a bottle was sunk to that depth and then closed by a mechanical device acting upon a metallic cork. The bottle was then brought to the surface. On releasing the cork the gas rushed out of the water with brisk effervescence, just as when a cork is withdrawn from a bottle of soda-water. It is clearly not practicable to bottle a natural mineral water on anything like the large scale occasioned by public demand in the manner described in this experiment and so water and gas must be temporarily separated and brought together again as nearly as possible at the same pressure. The water is drawn from a depth of 50 feet and subsequently it is re-united with gas at a pressure corresponding with that known to exist at this depth in the spring. So far as the relationship of gas and water is concerned, therefore, it is the same whether it is the water in bottle at a pressure of two and a half atmospheres or in the spring under a columnal pressure of water at 50 feet plus one atmosphere.

But, as has been indicated already, the water during storage develops a very slight sediment on exposure to air which is due to the oxidation of the salts of iron and subsequent separation of ferric hydroxide. If Apollinaris water direct from the spring were placed in a bottle and corked this change would be inappreciable, and in fact the system of storage has not so much for its object the separation of traces of iron as to provide a sufficient volume of the water for bottling purposes. Otherwise there is no reason why the water should not be put in the bottle straight from the spring. A few specks of iron would be found adhering to the bottle, the water itself would be quite clear, and, as a matter of fact, the composition of the water of the spring is not appreciably affected by this system of storage.

The bottling of Apollinaris water, however, entails a precautionary measure which alters, though only slightly, its composition in one respect. We refer to the addition of salt, the amount added over and above that normally present in the spring being one gramme per litre, as will appear from the difference between the results of our analysis, as regards salt, of the water direct from the spring and of the bottled water or the water as it leaves the tank. There is only one reason, and that a very good one, for adding this small quantity of salt to Apollinaris water prior to bottling. The addition of salt is found necessary in order to provide against the decomposition of the sulphate of sodium. In contact with a bad cork and in warm climates some reduction of the sulphate to sulphide is apt to be effected and the gas acting upon sulphide would set free sulphuretted hydrogen which would of course impart an objectionable taste to the water. By adding one gramme of salt per litre, or about nine grains to the pint, the water is preserved from undergoing this change. The salt used for this purpose, as our analysis shows, is of the purest description. The small quantity used does not affect the taste in the smallest degree; a difference in taste would be perceptible between pure distilled and distilled water containing a small quantity of common salt, but in a water containing carbonate of sodium, magnesium, lime, and already some com[illegible] the addition of salt in [illegible] all to the taste. The [illegible] though not the rule is an exception (occasioned perhaps by a defective cork or by warm weather, or most probably by both) which has to be provided against. Formerly the corks were salted but that only led to inconsistencies in the composition of the water and also the preservative effect *desired was not always gained, whereas by adding a perfectly* definite though quite small quantity of salt to the water a uniform result was obtained and according to a number of analyses which we have made of Apollinaris water purchased from different places the quantity of salt is remarkably constant. To sum up, Apollinaris reaches the public in a condition slightly different from the water at its source in two unessential respects which refer not to the water and the gas, which are both absolutely the natural products of the spring but to the mineral constituents. One constituent is partly eliminated during storage and another is put in which slightly augments the amount already normally present. The other constituents remain perfectly intact. Before bottling iron is deposited and salt is added to the extent that the amount normally present in the water direct from the spring—namely, 0·4212 gramme per litre—is increased to 1·4212 grammes per litre (or from three and a half grains to 12½ grains per pint). The exact way in which a small addition of salt thus effectually prevents the reduction of sulphates to sulphides is not known but the decomposition does not occur in mineral waters containing sulphates in which the amount of salt naturally present is over one gramme per litre. The Apollinaris Company has always published this simple means of protecting Apollinaris water from this risk.

Analysis of a sample taken directly from the spring at Neuenahr *by our Commissioner gave the following results*:—

ANALYSIS NO. 1.

Silica	0·080	grammes per 10 litres.
Iron	0·090	,, ,,
Sodium chloride	4·212	,, ,,
Sodium carbonate	12·213	,, ,,
Sodium sulphate	2 800	,, ,,
Calcium carbonate... ...	2 450	,, ,,
Magnesium carbonate ...	4 875	,, ,,
Total saline constituents	26 720	

To these results may be added the following as exemplifying the excellent sanitary state of the water;—

Free ammonia	0·0224	grains per gallon.
Albuminoid ammonia	0 0028	,, ,,

The water taken directly from the spring is absolutely sterile, yielding no growth whatever when sown on suitable nutrient media. The residue gives no sign of containing objectionable organic matter and on ignition does not carbonise in the slightest degree.

The opportunity was taken whilst our Commissioner was at Neuenahr of committing to evaporation on the spot 20 litres of the wa[illegible] Apollinaris spring. In this way [illegible] weighing, after being dried at 100° C., exactly 54·101 grammes, which is equal to 27·050 grammes from 10 litres, a number that will be seen to be in close agreement with that recording the total saline constituents in Analysis No. 1, which was conducted in THE LANCET Laboratory. The salts so obtained were finely powdered and intimately mixed and submitted to analysis and the following results expressed in parts by weight per cent. were obtained:—

ANALYSIS NO. 2.

Percentage Composition of Salts from 20 Litres.

Silica	0·90
Iron	0·70
Sodium chloride...	15·93
Sodium carbonate	46·65
Sodium sulphate	10·35
Calcium carbonate	9·00
Magnesium carbonate	16·47
	100 00

The indication for lithium was distinct, though subsequent examination showed the amount to be small. There were present also traces of bromine, strontium, and arsenic. In spite of the small quantity of lithium present this metal was detected in every sample of Apollinaris water examined, including bottles purchased at different shops in London.

The next sample was taken from a tank into which the water direct from the spring and slightly warm was being discharged after the addition of salt:—

ANALYSIS NO 3.

Iron	0·008	grammes per 10 litres.
Sodium chloride	13·700	,, ,,
Sodium carbonate	13·144	,, ,,
Sodium sulphate	2·860	,, ,,
Calcium carbonate... ...	1 850	,, ,,
Magnesium carbonate ...	4·280	,, ,,
Total saline constituents	35 842	

As will be seen from a comparison of Analysis No. 1 the amount of salt is increased to an amount identical with that subsequently shown to exist in the bottled water. The salt is added in the form of a solution and according to our analysis the salt so dissolved is practically pure sodium chloride. The analysis was as follows:—

ANALYSIS NO. 4.

Sodium chloride	99·562 per cent.
Calcium chloride	0·183 ,,
Sodium sulphate	0·255 ,,
	100·000

It thus contained over 99½ per cent. of pure chloride of sodium and is beautifully clean, white, and crystalline.

The next analysis refers to the sample taken from the tank after an exposure to the air of seven days:—

ANALYSIS NO. 5.

Iron	Trace.	
Sodium chloride	13·740	grammes per 10 litres.
Sodium carbonate	13·140	,, ,,
Sodium sulphate	2 860	,, ,,
Calcium carbonate... ...	1 450	,, ,,
Magnesium carbonate ...	4·610	,, ,,
Total saline constituents	35 800	

The tank contained about 12,000 litres of water and after emptying it a trifling deposit was scraped on the walls and floor which was found to weigh when dried at 100° C. 0·402 gramme. Its percentage composition is given below.

ANALYSIS NO. 6.

Moisture	4 00
Water of hydration	12 68
Silica	2·90
Iron	43·40
Calcium carbonate	35·90
Magnesium carbonate	0 84
Arsenic (As_2O_3)	0·12
Phosphoric acid (P_2O_5)	0·16
	100·00

It is interesting to notice that the iron carries with it during precipitation a distinct but minute quantity of arsenic. Roughly speaking, however, this deposit consists of one half oxide of iron and one half calcium carbonate. This represents all that is eliminated from Apollinaris water during seven days' storage in the tanks. The quantity per litre amounts to about 0 0335 gramme of ferric oxide and carbonate of lime or three-tenths of a grain per pint.

The following analysis was made of the water bottled and taken straight from the filling machine:—

ANALYSIS NO. 7.

Iron	Slight trace.	
Sodium chloride	13·747	grammes per 10 litres.
Sodium carbonate	12·062	,, ,,
Sodium sulphate	2·560	,, ,,
Calcium carbonate	2·250	,, ,,
Magnesium carbonate ...	4·881	,, ,,
Total saline constituents	35·500	

These results express the composition of Apollinaris water as it comes upon the table and it will be seen that except as regards iron (of which the amount was hardly perceptible) and salt the results are practically identical with the analysis

(No. 1) of the water taken from the spring. The amount of salt occurring naturally in the water is 4·212 grammes, while the amount in the bottled water ready for export is 13·747 grammes per ten litres, a difference of 9·535 grammes of salt, which represents the amount added for preserving purposes.

Subsequent analysis of Apollinaris water bought in the shops proved it to contain practically the same amount of salt which, in fact, varies within very trifling limits. On the whole, the results of analysis in regard to salt may be said to be remarkably constant in the case of the whole of the samples examined.

The total quantity of gas found in one bottle of Apollinaris water was found to be approximately three times the volume of water. Thus, a bottle containing 740 cubic centimetres of water gave off at ordinary temperature and pressure 1320 cubic centimetres of gas. Since one volume of water holds one volume of carbonic acid gas in solution at one atmosphere pressure the total gas in this case would amount to 740 cubic centimetres (in solution), 1320 cubic centimetres (discharged)—i.e., a total of 2060 cubic centimetres, or a volume nearly three times that of the water, which is exactly the quantity of gas contained in the water of the spring at a depth of 50 feet—that is, where the pressure (columnal and atmospheric) is equal to three atmospheres.

Two different samples of the gas gave respectively the following results on analysis :—

(1) 99·50 per cent. CO_2.
(2) 100·00 ,, ,,

Analyses were also made of the gas discharged from several bottles of Apollinaris water obtained in London and the following results were ascertained :—

99·60 per cent. CO_2.
99·75 ,, ,,
99 50 ,, ,,

The residue of gas, amounting on the average to about ½ per cent., contains air and possibly also argon and the rarer gases.

Recent investigations would appear to show that all natural mineral waters which evolve gas are radio-active. If that proves really to be the case and the radio activity is found to be permanent we may hope to possess some means of determining whether a given mineral water is a natural or artificial preparation. Experiments in this direction in regard to Apollinaris as well as upon the point of the possible presence of helion and other rare gases would be of considerable interest.

It only remains to add the analyses made independently in THE LANCET Laboratory of various samples of Apollinaris water obtained at different places in London. They serve to show the constancy of composition of the water wherever it is obtained and that it is identical with the water taken directly from the spring by our Commissioner except, as already stated, in regard to a trifling quantity of iron lost during storage in the tanks and an addition of salt (0·1 per cent.) which is advisable in order that the condition of the water at the spring may be preserved.

ANALYSES OF SAMPLES PURCHASED AT DIFFERENT SHOPS.

	(1)	(2)	(3)
Iron	Slight trace	Slight trace	Slight trace
Sodium chloride	13 800	13·680	13·510
Sodium carbonate	13·640	12·190	12·914
Sodium sulphate	3·016	2·895	2·852
Calcium carbonate	2·000	2·100	2 500
Magnesium carbonate ...	5·030	5·030	5 024
Total saline constituents (grammes per 10 litres)	37·486	35·895	36·800

Lithium was detected in every sample examined and the following results in regard to saline and albuminoid ammonia are interesting in indicating that the water undergoes no departure from its admirable state of organic purity at the spring during the process of bottling and exportation.

	Water direct from spring (grains per gallon).	Water purchased in London (grains per gallon).
Free ammonia	0 0224	0 021
Albuminoid ammonia ...	0·0028	0·0042
Nitrogen in nitrites and nitrates	*Nil.*	*Nil.*
Residue on ignition ...	No charring.	No charring.

In conclusion it is difficult to suggest, in the face of the facts just recorded and of the experience which has decided upon the adoption of the methods of bottling Apollinaris which we have described, how those methods could be altered with any possible advantage to the public or how any modification of those methods would enable the public to receive the water in a condition more natural than it is. As a matter of fact Apollinaris water is bottled in such a way that the natural equilibrium of the water and its complement of gas at a depth of 50 feet in the spring are preserved in the bottle for public use. Both water and gas are absolutely the natural products of the spring and the composition of the bottled water is, according to our analysis, always the same and without any appreciable variation in the mineral constituents. Some portion of a useless constituent, in the form of oxide of iron (the total amount in the water being quite minute) separates from the water prior to bottling but a useful constituent, in the shape of a small quantity of salt, is added to augment the amount of salt already naturally present in the spring in order to prevent the possible decomposition to which the sulphate of sodium of the water is occasionally liable. The taste of the water in bottle is identical with that of the water taken directly from the spring. Apollinaris water has a peculiar soft flavour which is due not to common salt at all but in part to the alkaline carbonates which neutralise the acids in the mouth, and in part to the natural state of combination of the mineral ingredients. As Professor Oscar Liebreich has said, "even the best manufactured artificial mineral waters differ from the natural ones in taste and value." There is nothing disclosed in our analysis of the bottled water which is not found in the water at the spring. In view of these facts which we have taken some trouble to ascertain for ourselves, it seems to us that the recent decision of the Lord Chief Justice that Apollinaris water is entitled to the description of a natural mineral water is in accordance with both law and common sense.

We may add that our analyses and observations are in substantial agreement with those given at various times by the late Professor Virchow, Professor Bischof, Professor Liebreich, Professor Mohr, Professor Hofmann, Professor Kekulè, Professor William Odling, and the late Sir Edward Frankland.

THE RETIRING AGE FOR PROFESSORS, PHYSICIANS, AND SURGEONS.

IN his presidential address to the Congress of American Physicians and Surgeons,[1] held at Washington on May 12th, 13th, and 14th, 1903, Professor W. W. Keen makes the following remarks on an age limit for college professors and hospital physicians and surgeons which in view of the leading article published in THE LANCET of Jan. 16th, p. 169, we think will be of interest to our readers :—

"One of the difficult questions which boards of trustees have to face is whether there shall be a fixed age at which a college professor or a hospital physician or surgeon shall retire from the active duties of his post. I firmly believe that they should fix such a retiring age in the interest of the students and the patients. As age advances a man's opinions and his practice become 'as petrified as his arteries.' He is incapable of constant study, of adding to his knowledge, or of keeping up with the feverish strides of medicine. He ought then to be relieved of his cares and his duties. If no rule exists he is allowed to continue his inefficient or even disastrous work or by some harsh suggestion is compelled to give place to another more competent man. A rule is a condition accepted when he is appointed, and just as in the army and navy when an officer reaches 64 or 62 years of age, he is retired on reduced pay, and because it is a rule he does not feel hurt or humiliated; so, in a college or hospital, when time and the rule bring us to the period when we must gracefully retire no one's reputation is injured or his feelings lacerated.

"I have ascertained that the following rules are in force in some of the larger institutions :—

"At Harvard the age when a professor may request to be retired is 60 years, provided he has been in the service of the University for 20 years with a reduced pay ranging from one-third to two-thirds of his salary. At 66 years of age he may be retired by the President and Fellows partly or wholly. The details of the plan are admirably arranged.

---

[1] The Duties and Responsibilities of Trustees of Public Medical Institutions, being the presidential address delivered to the Congress of American Physicians and Surgeons, 1903, by W. W. Keen, M.D., LL.D., F.R.C.S. (Hon.), Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College, Philadelphia (Transactions of the Congress, p. 232).

"At Chicago, while no plan is yet in force, largely, I presume, because of its recent establishment on the present basis, such a plan will soon be made operative.

"At Columbia the retiring age, after 15 years of service, is 65 years, either at the request of the professor or upon motion of the trustees, and on half pay.

"At Yale the retiring age is 65 years after 25 years of service and on half pay, but the retirement is not compulsory. It will probably be made compulsory before long.

"At Cornell the retiring age is 70 years, but the Pension Fund will not be available until 1914. The retiring pension will then be $1500.

"At the University of Pennsylvania and at Johns Hopkins no retiring age is fixed.

"The only hospitals I know of in which a retiring age is fixed are the Massachusetts General Hospital and the Boston City Hospital. At the former the compulsory retiring age of the surgeons is 63 and of the physicians 65. At the Boston City Hospital the visiting surgeons are retired at 65 but the physicians, gynæcologists, and all the other medical officers continue in service indefinitely—a very curious anomaly.

"These varying, but in the main identical, provisions, when any exist, show the trend of thought and practice. They generally apply to the medical department, except that in case a professor is engaged in the practice of his profession, and so has a private income, the provision for continuing a portion of his salary does not apply. This is right and fair. Of course, in all hospitals where there are no salaries no provision as to reduced salary would obtain.

"The point I wish to emphasise is, however, that the age limit (which in my opinion should be 65 years) should be *compulsory* and so not be invidious in any given case. It will be objected that not a few men are in full intellectual and physical vigour at the age of 65 years and it will be a detriment to the institution to lose their services when their ripe experience and admirable teaching are most desirable. I admit it. But for every one such case of harm done by compelling a man to stop there are a score of instances of men who are doing vast injury by their inefficiency. Moreover, in the very few cases in which it might be allowable, as boards of trustees make rules they can unmake them, and in special cases they could pay a graceful compliment and preserve to the institution their exceptional men by extending the limit to 70 years. In no case can I think it wise to go beyond this limit."

MEDICINE AND THE LAW.

The Colouring of Foodstuffs.

SIX tradesmen were fined at the South-Western police-court on Jan. 21st for selling preserved peas containing crystallised sulphate of copper in varying proportions, added to them for the purpose of dyeing them a more brilliant green than they would otherwise have been. In defence it was stated that the public demanded that peas should be green and would not buy them unless they were. The obvious answer to this is that the public asks for green peas because it associates that colour with fresh well-cooked vegetables and not because it desires to absorb sulphate of copper. That the public has an unreasoning faith in certain appearances with regard to its food as indicative of good quality is well known. In London in particular it likes milk and butter coloured with anatto and bread of an unnatural and unnecessary whiteness. Jams also are readily bought of a colour which the ordinary process of cooking sound fruit with sugar could not produce. A few weeks ago evidence was given at the City of London court of a fish-dealer having recommended a retailer to "try cochineal" in order to impart to an unclean salmon the colour of a fresh run fish. If he meant what he said to be taken seriously he must have held the opinion that the consumer would rely upon his eye rather than upon his palate.

Garbage-mongers Fined and Imprisoned.

At the South-Western police-court on Jan. 21st a man named Carl Hetzel was convicted of having pork which was unfit for human food upon his premises for the purpose of making it into sausages. He was fined £10 with costs. On the same day at the Guildhall police-court Frederick Cutting, a pig-dealer of Roper's green, Hadleigh, Suffolk, was charged with sending eight diseased pigs to Smithfield Market. In this case the knowledge of the defendant with regard to the condition of the animals was proved by the evidence of the man who had sold them to him and to whom he had observed that they had the cramp and looked "a bit lungy." On account of their condition he had offered 50*s*. for ten, and eventually had bought nine for 53*s*. The after-history of the ninth pig was not reported. A previous conviction was proved against Cutting, after which it is not surprising to learn that he was sent for six weeks to a place where the food, if not luxurious, will be more wholesome than that which he endeavoured unsuccessfully to place upon the London market.

The Wording of the Medical Certificate of the Cause of Death.

We have received the following letter:—

To the Editors of THE LANCET.

SIRS,—I should be glad of an o
placed on the passage, "I heret
during h—— last illness." Shou
certificate of death in the case of
at 6 A.M. the next morning and n
death was probably broncho pneu
nearly a week I can hardly be
illness.

Jan. 17th, 1904. AORTA.

Incidents such as that referred to above are not uncommon and the medical man has to exercise his discretion with regard to them. The words of the Act which impose upon him the obligation to give a death certificate are as follows: "In the case of any person who has been attended during his last illness by a registered medical practitioner that practitioner shall sign and give to some person required by this Act to give information concerning the death a certificate stating to the best of his knowledge and belief the cause of death, and such person shall when giving information concerning the death, or giving notice of the death, deliver that certificate to the registrar, and the cause of death as stated in that certificate shall be entered in the register together with the name of the certifying medical practitioner" (37 & 38 Vict., c. 88, section 20, subsection 2). The mere fact of the medical man seeing the patient on one occasion only during the illness from which he dies does not, according to this section, affect the matter. In the ordinary construction to be put upon the words used he "attends the deceased during his last illness," and the question for him to decide is whether he can certify "to the best of his knowledge and belief the cause of death." If the opportunity for observation has been insufficient or if the disease has remained obscure so that he neither "knows" nor has formed any "belief" upon the subject, he is not under the obligation to certify and should not do so. Doubt may occur whether he has attended during the fatal illness once or many times. In any particular case, however, it may be the duty of the medical practitioner not to certify, although the "cause of death," strictly speaking, is clear to him. He may be of the opinion that the death which has been the result of well-defined physical conditions would not have taken place but for the neglect to summon medical aid before it was too late. He may further have reason to suspect that this neglect was deliberate and that he was only summoned in order that he might certify a death into which the coroner should inquire. In the case of children parents are not always anxious that they should survive or escape illness, and it is not impossible to expose children to cold or wet so that they may become ill and their lives may be eventually in danger. It is a matter for regret that the coroner is not bound to hold an inquest on all occasions where there is no medical certificate of the cause of death, but as the law stands inquests are only for cases of "violent or unnatural death, or of sudden death where the cause is unknown." A death caused by neglect is not a "natural" death and for this reason a medical man, where he has any ground for suspecting that matters are not, to use a convenient phrase, "all right," should decline to certify and should leave the matter to the coroner, upon whom the responsibility will then rest. In all cases he must exercise his discretion, taking into consideration all the facts connected with the death so far as he is aware of them.

Salisbury v. *Gould.*

In Salisbury v. Gould, recently tried in the King's Bench Division before Mr. Justice Grantham and a special jury, Mr.

W. R. Gould, a medical man practising in Lamb's Conduit-street, successfully defended an action in which damages were claimed against him on the ground of negligence and he is heartily to be congratulated upon the verdict obtained. Mr. Gould had in September, 1901, certified a little girl to be suffering from small-pox but after she had been placed in an observation shed at Rotherhithe for three days the conclusion was formed that her condition was due to chicken-pox and she was restored to her mother. The evidence showed that, so far from treating the case with anything approaching negligence, Mr. Gould had exercised considerable caution, visiting the patient twice, on Sept. 1st and 2nd, before calling the attention of Dr. W. A. Bond, the medical officer to the Holborn borough council, to the case. Dr. Bond had then examined the patient thoroughly and it was after consultation with him and not until he had secured his approval of the step to be taken that Mr. Gould gave the certificate and the child was removed on Sept. 5th. The evidence further showed that the symptoms pointed strongly to small-pox rather than to chicken-pox. It is a little surprising to see that a medical witness was called, apparently as an "expert," in support of the plaintiff's case and according to the *Times* report of his evidence, deposed that he thought it impossible to mistake chicken-pox for small-pox, at all events after a few hours' development of the illness. The jury do not appear to have given much weight to his testimony, for after Dr. Bond had corroborated Mr. Gould they intimated that they had heard enough of the case and returned a verdict for the defendant, for whom judgment was accordingly given. In addition to this gratifying decision given by the jury Mr. Gould was also entitled to judgment in his favour under the Public Authorities Protection Act, 1893 Mr. Justice Grantham intimated that this was his view but suggested the taking of the jury's verdict as a precaution in case on appeal he should be found to be wrong. The statute referred to provides that "where any action, prosecution, or other proceeding is commenced against any person for any act done in pursuance, or execution, or intended execution of any Act of Parliament or of any public duty or authority or in respect of any alleged neglect or default in the execution of any such act, duty, or authority, the action, prosecution, or proceeding shall not lie or be instituted unless it is commenced within six months after the act, neglect, or default complained of or in case of a continuance of injury or damage within six months after the ceasing thereof." This certainly appears to cover the case of a medical practitioner certifying under the Public Health Acts, although called in to treat the patient in the course of his ordinary practice. A medical man in such circumstances has an unpleasant duty to perform and little enough to protect him from attack when through no fault of his own he lays himself open to it. It would be doubly hard if he were allowed to be at the mercy of a plaintiff several years after the event. At the same time it is not easy to see in what way the Public Authorities Protection Act afforded any practical protection to Mr. Gould. At all events it did not prevent him from being exposed to the anxiety, the expense, and the loss of time entailed by an action persevered in until the jury refused to hear any more of it.

ASYLUM REPORTS.

London County Asylum, Cane-hill (Report for the year ended March 31st, 1903).—The average number of patients resident during the year was 2139, comprising 924 males and 1215 females. The admissions during the year amounted to 323—viz , 181 males and 142 females. Of these 277 were first admissions. Mr. James M Moody, the medical superintendent, states in his report that "a considerable number of the admissions, in regard to prospect of recovery, were of much the same hopeless class as in recent years." A large proportion of those received were in an advanced state of senility or suffering from epilepsy, general paralysis of the insane, and other forms of organic brain disease. The number of patients discharged as recovered during the year amounted to 132—viz., 69 males and 63 females, or 6·17 per cent. of the average number resident. The deaths during the year amounted to 158, or 7·38 per cent. as calculated on the same basis. "This death-rate is," says Mr. Moody, "below the average death rate of the county and borough asylums in England and Wales." Post-mortem examinations were made in 146 cases, or 94·4 per cent. of the deaths. Of the deaths four were due to epilepsy, seven to senile decay, ten to renal disease, 14 to pneumonia, 17 to cardiac disease, 24 to pulmonary and other forms of tuberculosis, 29 to general paralysis of the insane, and the rest to other causes. A severe epidemic of influenza prevailed in the institution towards the latter part of 1902, 26 male and 127 female patients and 31 members of the staff being attacked. A female patient (a single woman) admitted whilst pregnant was safely delivered of a male child who was afterwards removed to the workhouse. "The mother remains an inmate of the asylum." A commodious balcony has been erected in connexion with the first floor of the male infirmary whereby helpless patients can be given the benefit of open-air treatment. The Commissioners in Lunacy state in their report that the wards were found to be cheerful and comfortable, that the dormitories were clean and well ventilated, that there was an air of general contentment about the patients who were quiet and orderly. and that the medical case-books and records were well kept. The committee of management states in its report that the structural alterations carried out during the year include the erecting of fire escape windows in the male and female blocks D2 and that other precautions have also been taken against fire. The farm and garden accounts show a debit balance of £430 10*s*. on the year's working, this being mainly due to an outbreak of swine fever which necessitated the slaughter of a large number of pigs. The practice of subjecting the cows purchased to the tuberculin test has been continued with satisfactory results.

Fife and Kinross District Asylum (Report for the year ending July 31st, 1903).—The average number of patients resident during the year was 550, comprising 261 males and 289 females. The admissions during the year amounted to 137—viz , 74 males and 63 females. Of these 101 were first admissions. Dr. A. R. Turnbull, the medical superintendent, states in his report that "the most striking feature of the year's admissions was the large number and the very unfavourable nature of the male cases." Of the 74 male admissions no fewer than 12 were cases of general paralysis. "It is often said," adds Dr. Turnbull, "that general paralysis has become distinctly more frequent of late years, and our figures, though by themselves too small to allow of any definite conclusion, bear out in this respect the experience of other asylums. There is reason to believe that general paralysis is a sequel of syphilitic infection or of vicious indulgences which destroy the natural healthy tone and disease-resisting power of the constitution, and is therefore largely an avoidable disease; and the frequency of its occurrence has thus a very grave and serious meaning in reference to the mode of life and habits of many of the general population." The number of patients discharged as recovered during the year amounted to 41—viz, 19 males and 22 females, or 7 4 per cent. of the average number resident. The deaths during the year amounted to 32, or 5 8 per cent. as calculated on the same basis. Of the deaths three were due to influenza, three to pulmonary and other forms of tuberculosis, four to bronchitis and broncho pneumonia, five each to cardiac disease and senile decay, six to general paralysis of the insane, and the rest to other causes. Extensions of the buildings to accommodate additional cases are in progress and additions have been made to the houses occupied by the head male attendant and clerk of works. Precautions have been taken and additional exits provided against outbreaks of fire. The rate of board for parochial cases has remained at £25 per annum *per patient*. The farm operations have been favourable and the accounts show a profit of £768 for the year. The Commissioners in Lunacy state in their report that owing to increase in the admissions the present accommodation of the asylum is taxed to the utmost, so that the extensions now in progress to accommodate 50 males and 50 females have not been started a moment too soon, that the institution was in excellent order and scrupulously clean, that the inmates were neatly and suitably clothed, that the bedding and sleeping rooms were in good condition, and that the medical books and records were accurately and regularly kept. The committee of management states in its report that steps for installing electric light in place of gas had been taken in the summer of 1903.

VITAL STATISTICS.

WE have received from the Registrar-General the following figures relating to the year 1903 which are extracted in advance of publication from his quarterly return. These figures will be appreciated by medical officers of health who need them for their annual report to the Local Government Board.

—	Annual rate per 1000 living.			Infant mortality. Annual death-rate of infants under one year per 1000 births.
	Births.	Deaths.	Death-rate seven chief epidemic diseases.	
England and Wales	23 4	15 4	1 46	132
76 great towns ...	29 7	16 3	1·89	144
103 smaller towns ...	27 4	14·6	1·41	135
Rural England ...	27·3	14 8	1·08	118

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8718 births and 5304 deaths were registered during the week ending Jan. 23rd. The annual rate of mortality in these towns, which had been 20 6 20·3, and 19 0 per 1000, further declined last week to 18·1 per 1000. In London the death-rate was 17·4 per 1000, while it averaged 18·4 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 2·3 in King's Norton, 7·1 in Hornsey, 8·7 in Barrow-in Furness, 10·3 in East Ham, 11·3 in Bournemouth, and 11·8 in Leyton and in Hastings; while the highest rates were 22·6 in West Ham, 22·8 in Liverpool, 23·2 in Wigan, 23·6 in Tynemouth, 24·0 in Stockton-on-Tees, 25·0 in Great Yarmouth, 29·5 in Preston, and 39·4 in Merthyr Tydfil. The 5304 deaths in these towns last week included 427 which were referred to the principal infectious diseases, against 495, 462, and 450 in the three preceding weeks; of these 427 deaths 121 resulted from whooping-cough, 114 from measles, 66 from diarrhœa, 64 from diphtheria, 36 from scarlet fever, 25 from "fever" (principally enteric), and one from small-pox. In Hornsey, Southampton, Norwich, Wolverhampton, Aston Manor, Birkenhead, Huddersfield, Halifax, and in eight other smaller towns, no death from any of the principal infectious diseases was registered, while they caused the highest death-rates in West Bromwich, Burnley, Preston, Gateshead, Rhondda, Merthyr Tydfil, and Swansea. The greatest proportional mortality from measles was recorded in West Ham, Warrington, Preston and Rotherham; from diphtheria in St Helen's and Rochdale; from whooping-cough in Rochdale, West Hartlepool, Gateshead, Newport (Mon.), Rhondda, Merthyr Tydfil, and Swansea; and from diarrhœa in West Bromwich. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. One fatal case of small-pox was registered last week in Gateshead, but not one in any other of the 76 large towns. The Metropolitan Asylums hospitals contained 24 small-pox patients on Saturday last, Jan. 23rd, against 26 on each of the three preceding Saturdays; three new cases were admitted during the week, against four, six, and four in the three preceding weeks. The number of scarlet fever cases remaining under treatment in these hospitals and in the London Fever Hospital, which had been 1632, 1659, and 1660 at the end of the three preceding weeks, had further risen to 1677, at the end of last week; 178 new cases were admitted during the week, against 194, 201, and 195 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 404, 433, and 406 in the three preceding weeks, declined last week to 353, and were 58 below the number in the corresponding period of last year. The causes of 78, or 1 5 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Bolton, Salford, Bradford, Cardiff, and in 39 other smaller towns; while the largest proportions of uncertified deaths were registered in Northampton, West Bromwich, Liverpool, St. Helen's, Blackburn, Sheffield, Sunderland, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 21·7, 23·2, and 20·2 per 1000 in the three preceding weeks, further declined to 19·8 per 1000 during the week ending Jan. 23rd, but was 1·7 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 12·0 in Greenock and 14·9 in Paisley, to 25 2 in Dundee and 26 2 in Perth. The 655 deaths in these towns last week included 19 which were referred to measles, 14 to diarrhœa, 11 to whooping-cough, four to "fever," three to diphtheria, two to small-pox, and one to scarlet fever. In all 54 deaths resulted from these principal infectious diseases last week, against 71, 53, and 63 in the three preceding weeks. These 54 deaths were equal to an annual rate of 1·6 per 1000, which was slightly above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been 26 13, and 23 in the three preceding weeks, declined again last week to 19, of which 13 were registered in Glasgow and five in Dundee. The deaths from diarrhœa, which had been 21, 15, and 13 in the three preceding weeks, rose again to 14 last week, and included five in Glasgow, four in Edinburgh, three in Aberdeen, and two in Dundee. The fatal cases of whooping-cough, which had been 15 in each of the two preceding weeks, declined last week to 11, of which four occurred in Edinburgh, two in Glasgow, and two in Leith. The deaths referred to different forms of "fever," which had been three in each of the two preceding weeks, increased to four last week and included three in Glasgow. The three fatal cases of diphtheria corresponded with the number in each of the two preceding weeks and were all registered in Glasgow. The deaths from small-pox, which had been five, three, and five in the three preceding weeks, declined again last week to two, both of which occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 177, 213, and 198 in the three preceding weeks, further declined last week to 167, and were 16 below the number in the corresponding period of last year. The causes of 27, or more than 4 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 31·8, 27·8, and 28·8 per 1000 in the three preceding weeks, declined again to 26·0 per 1000 during the week ending Jan. 23rd. During the past four weeks the death-rate has averaged 28 6 per 1000, the rates during the same period being 19 2 in London and 18 7 in Edinburgh. The 189 deaths of persons belonging to Dublin registered during the week under notice, showed a decline of 20 from the number in the preceding week and included eight which were referred to the principal infectious diseases, against 16, 23, and ten in the three preceding weeks; of these, five resulted from whooping-cough and three from "fever," but not one from any other of the principal infectious diseases. These eight deaths were equal to an annual rate of 1·1 per 1000, the death-rates last week from the principal infectious diseases being 1·4 in London and 1·3 in Edinburgh. The fatal cases of whooping cough, which had been 12, nine, and five in the three preceding weeks, were again five last week. The deaths referred to different forms of "fever," which had been two, five, and two in the three preceding weeks, rose again last week to three. The 189 deaths in Dublin last week included 40 of children under one year of age and 54 of persons aged 60 years and upwards; the deaths of infants showed a marked excess over the number in the preceding week, while those of elderly persons were considerably fewer. Five inquest cases and four deaths from violence were registered, and 67, or more than a third, of the deaths occurred in public institutions. The causes of 11, or nearly 6 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: E. W. Luther to the *Cæsar* and J. S. Lambert to the *Victorious* (dated Feb. 2nd, 1904) Surgeons D. P. Chapman to the *Victorious* and A. C. Bean to the *Cæsar* (dated Feb. 2nd, 1904); G. R. MacMahon to the *Leander* (dated Jan. 21st, 1904); and R. A. Ross to the *Vivid* (dated Feb. 14th, 1904).

ROYAL NAVAL VOLUNTEER RESERVE.

The undermentioned gentleman has been appointed an Honorary Surgeon—viz, Charles O'Brien Harding (dated Jan. 18th, 1904).

ROYAL ARMY MEDICAL CORPS.

Lieutenant O. Challis, from temporary half-pay, to be Lieutenant (dated Dec. 24th, 1903). Lieutenant O. Challis to be Captain (dated Dec. 24th, 1903).

Lieutenant-Colonel E. L. Maunsell is specially selected for increased pay under Article 365 Pay Warrant. Lieutenant-Colonel P. Mulvany succeeds Lieutenant-Colonel W. J. R. Rainsford, C.I.E., as medical officer in charge of the Princess Louise Hospital at Alton. Lieutenant-Colonel C. R. Tyrell is posted to the South-Eastern District for duty.

INDIAN MEDICAL SERVICE.

The following is a list of the successful candidates at the Indian Medical Service examination held on Jan. 19th and four following days:—

	Marks.		Marks.
H. B. Drake	3515	I. D. Jones	2834
E. C. Hodgson	3167	H. Watts...	2810
W. S. McGillivray	3046	J. Anderson	2800
W. Gillitt	2991	W. T. Finlayson	2799
W. F. Brayne...	2978	H. E. Stranger-Leathes ...	2792
M. S. Irani	2899	E. A. Roberts	2789
S. W. Jones	2882	G. G. Hirst	2777
W. Tarr	2874	M. J. Quirke	2753
C. H. Barber	2867	J. M. Holmes	2684
W. T. McCowen	2839	M. F. White	2666

42 candidates (of whom 26 had University degrees) competed for 20 vacancies.

ROYAL ARMY MEDICAL CORPS (MILITIA).

Scottish District Company: Lieutenant (Honorary Lieutenant in the Army) W. V. Sinclair to be Captain (dated Dec. 19th, 1903).

VOLUNTEER CORPS.

Rifle: 1st Volunteer Battalion the Buffs (East Kent Regiment): Surgeon-Lieutenant C. K. Bowes to be Surgeon-Captain (dated Jan. 23rd, 1904). 1st Volunteer Battalion, the Worcestershire Regiment: Surgeon-Lieutenant B. Addenbrooke to be Surgeon Captain (dated Jan. 23rd, 1904). 1st Volunteer Battalion the Hampshire Regiment: Surgeon-Lieutenant D. L. Thomson to be Surgeon-Captain (dated Jan. 23rd, 1904).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Edinburgh Company: Lieutenant D. Waterston to command under paragraph 55A Volunteer Regulations (dated Jan. 23rd, 1904).

VOLUNTEER INFANTRY BRIGADE BEARER COMPANIES.

East Surrey: Surgeon-Captain (Honorary Captain in the Army) E. W. St. V. Ryan, from 16th Middlesex Volunteer Rifle Corps, to be Captain (dated Jan. 2nd, 1904).

ALUMINIUM FOR MILITARY PURPOSES.

M. Moissonnier, principal apothecary of the first class in the French army, having taken part in several campaigns in Algeria and Tunisia, became impressed with the great importance which is attributed by commanding officers to the alleviation of the burden that the soldier has to carry. He accordingly was induced to turn his attention to aluminium, of which metal he made a profound study, and has now embodied the results of his investigation in a small volume of 219 pages, the publisher being M. Gauthier-Villars of Paris. Although aluminium is almost as common in nature as iron it has not been utilised to any considerable extent until within the last few years. Until lately the cost *was prohibitive, 150 francs per kilogramme, but thanks to improved* methods of production, all of which are described by M. Moissonnier, the metal can now be obtained for three francs per kilogramme. At this price it is permissible to believe, he thinks, that aluminium can with advantage be made to take the place of iron in the manufacture of many of the articles of equipment in use in the army. A metal as hard as iron and only one-fourth of the weight of silver, which is moreover unaffected by exposure to air whether moist or dry, or by immersion in water whether hot or cold, which does not oxidise or tarnish like most common metals, withstanding even the action of sulphuretted hydrogen, cannot but have a great future before it. Experiments which have been conducted under the auspices of the French Minister of War in Oran and elsewhere have conclusively shown the superiority of aluminium utensils, culinary and otherwise, over those of enamelled iron. Not only were the former more durable and much more easily kept clean but also very much lighter. It was calculated that the weight carried by each soldier was reduced by about 600 grammes (one pound and a third) In addition to culinary utensils, including plates and dishes, the following portions of a soldier's equipment can with advantage be fabricated of aluminium or one or other of its alloys: helmets, saddle-trees, stirrups, spurs, scabbards, buckles, belt-clasps, buttons, watch and other chains, epaulettes, water-bottles, drinking cups, spoons and forks, bicycles, drums, and field guns. Aluminium can be soldered *to itself without the intervention of lead or any other metal* and is consequently eminently suitable for the fabrication of surgical instruments and appliances. In conclusion, M. Moissonnier deals with the various alloys of aluminium and describes his methods for their analysis.

ARMY RECRUITING.

Owing to a change consequent on the decision of the Secretary of State for War as to the time of rendering the annual reports on recruiting in future the report of the Inspector-General of Recruiting just issued only embraces nine months of the past year. The number of recruits raised for the regular army, excluding Colonial corps, for the nine months amounted to 29,324, and for the Militia to 25,774. These numbers show a large diminution on those of the corresponding period of previous years. This falling off is, however, largely to be accounted for by the fact that owing to the mounted corps having been specially recruited during the late war they were all of them at the end of it largely in excess of establishment—to say nothing of the effect of the changes that have been made in the conduct of recruiting for the army with the view of preventing the enlistment of undesirable characters. With regard to the physical standard, the measurement of recruits, eyesight, and artificial teeth, the results of the very limited experiment of the employment of dentists having been such as to lead to an anticipated extension of the scheme, the report contains a number of interesting and instructive remarks and comments. A good deal of official inquiry into these and other points has already been instituted and is still taking place. The large number of recruits lost to the service owing to their physical unfitness and the growing increase in the percentage of rejections on this ground are forcibly pointed out in the report. Major-General Sir F. Howard, the inspector-general of recruiting, tells us that "the matter has been very fully dealt with by the Director-General of the Army Medical Department and a conference took place in July last between representatives of the Admiralty and the War Office to consider the subject as affecting the two services. As a result of this conference the matter was brought to the notice of the Home Office and an inter-departmental committee has been appointed to consider the subject of the physique of the classes from which recruits are drawn for both the army and the navy, with a view of determining whether the whole question should be considered by a Royal Commission." The subject is one of great national importance, especially when, as in the case of Manchester, the medical rejections amount to 49 per cent.

THE ROYAL NAVY LIST.

The 105th quarterly issue of this work of reference, dated January, 1904, contains notices of appointments and promotions in the Royal Navy up to, and including, Dec. 23rd, 1903. The records of the war and meritorious services of the officers of the Royal Navy, Royal Marines, and Royal Naval Reserve occupy a large portion of the book, the careers of some 10,000 officers being dealt with. The list of the vessels in the Royal Navy, with their tonnage description, war record, and so on, forms a complete guide to *all ships* in commission, with their officers and present stations. A feature of the recent issues of the Royal Navy List is the carefully compiled record of the current history of our first line of defence. It is impossible in a short notice to enumerate all the matters of interest in connexion with the Royal Navy which find a place in this list and it must suffice to say that it is an indispensable work of reference to all who are in any way brought into contact with the Royal Navy. Messrs. Witherby and Co., 326, High Holborn, and 4, Newman's-court, Cornhill, are the publishers.

THE ROYAL ARMY MEDICAL CORPS MANUAL.

Surgeon-Major Reginald R Sleman, C.I.V., informs us that an extract from the manual for the Royal Army Medical Corps has recently been published giving important alterations in the drill. The movements are much simplified and are mostly in accordance with the changes adopted in infantry training. The words of command are more practical. The following movements have been abolished: extending at the halt, moving to a flank with sloped stretchers, and changing front The bearer company and field hospital camps are altered; in the former the tents are reduced to nine, two of the officers' tents and the guard tent being omitted, and in the latter two tents for general stores have been added, whilst the tents for the Army Service Corps have been reduced by two. Surgeon-Major Sleman, after stating that a combined camp for a bearer company and a field hospital has been authorised, says "perhaps we shall soon see the *personnel* also combined to form a 'brigade medical unit.'"

SURGEON-MAJOR G. H. DARWIN, LATE 2ND VOLUNTEER BATTALION THE MANCHESTER REGIMENT.

Surgeon-Major G. H. Darwin, who has recently retired from the 2nd Volunteer Battalion the Manchester Regiment, after 17 years' service in the Volunteer Force, has done much good work in the cause of first aid and has been connected with the St. John Ambulance Association for 25 years. A correspondent, writing to a lay contemporary, recalls the fact that some years ago Surgeon-Major Darwin was made a Knight of Grace of the Order of St. John of Jerusalem and says that, "in the interest of those who work for years as Dr. Darwin has done, it is befitting that some further recognition should be forthcoming as a reward for past service and as an incentive to other medical men to go and do likewise."

INDIAN REST CAMPS

According to the *Pioneer*, it seems that the Indian Government intends to abolish most of the halting places for troops known to all who have travelled in India as rest camps. We do not know the reasons which are causing the Indian Government to take this step, supposing it really to be contemplated. We should have thought that it was very desirable to have such places for the comfort and convenience of troops making long railway journeys, for example. So far as we know the rest-camp system has proved an effective, popular, and healthy system and we are consequently at a loss to understand why it should not be maintained, seeing that experience has been altogether in its favour.

THE TRAINING OF MILITIA RECRUITS AND VACCINATION.

The War Office in a recent memorandum issued to military districts announces that it has been decided that a militia recruit's training cannot be extended to make good the time lost through inflammation of the arm consequent on vaccination. Lord Roberts is of opinion that cases where men are totally incapacitated from work by vaccination are comparatively rare and that only in very exceptional circumstances need the training of a militia recruit be entirely suspended from causes attributable to his having been vaccinated.

ROYAL ARMY MEDICAL CORPS VOLUNTEERS.

The annual distribution of prizes won by the London Companies of the Royal Army Medical Corps Volunteers will take place at the headquarters of the corps, Calthorpe-street. London, W.C., on Feb. 6th, at 8 P.M. The proceedings will be followed by a dance.

PRESENTATIONS TO MEDICAL PRACTITIONERS—Mr. G. P. Rogg, M D. Aberd., L R.C.P. Lond., M R C.S. Eng., who has been the medical officer of the British Home and Hospital for Incurables at Streatham, London, S.W., for more than 24 years, recently received from the patients and nursing staff of the home a silver bowl.—On Jan 20th at Holmes Chapel, Cheshire, Mr. C. F Sutton, M.R C.S. Eng., was presented by his patients and friends with a silver soup tureen, together with a silver tea and coffee service and tray, as a token of esteem on his retirement from practice after nearly 40 years' residence.

Correspondence.

"Audi alteram partem."

ST. BARTHOLOMEW'S HOSPITAL.

To the Editors of THE LANCET.

SIRS,—Since our former letter was published by you in December, 1903, several events have occurred which are of importance to those interested in this institution; we are therefore again asking you to give publicity to our views on the present situation. We wish to emphasise the fact that the recent decision of the governors to extend our site, either by acquiring more land or by utilising adjacent land, already in our possession, on which to erect the nurses' home and the residential college for students meets with our unanimous approval and support. It has been alleged that the plans for rebuilding are not sufficiently advanced to enable any accurate estimates to be made and we should like, therefore, to say publicly that this is certainly not the case. The needs of the hospital for additional buildings were placed by us before our governors more than two years ago, and the fullest details of even the floor space required by individual departments were also given. This has enabled the hospital architects to supply estimates of the cost of the required buildings and the precise positions of the new blocks in a completed plan will not affect their conclusions.

It has always been the opinion of the medical council that all such additional buildings as they have asked for should be planned so as not to interfere with the rebuilding of the wards; and plans have now been submitted to us which support our views and show that a completely new hospital can be satisfactorily erected on our site of six and a half acres. It will thus be seen that, instead of St. Bartholomew's Hospital having no sufficiently settled plans or estimates, the latter are in an advanced state. We are, indeed, quite convinced that more than enough time has been already spent in preliminary considerations and we most heartily support the decision of the governors to issue an appeal at once, for we know better than others can possibly know how urgent is the need for prompt action.

There is another matter that has also attracted attention to which we desire to allude—namely, the situation of St. Bartholomew's. Its great accessibility is a matter of the very highest importance to the poor of London. So long as the City is the heart of London and of the empire, so long will access to it, and consequently to St. Bartholomew's, be cheap and easy, and so long will this charity remain a great consulting centre for the sick poor. The fact that its out-patients number about 150,000 in a year is a sufficient proof in itself of the usefulness of the hospital on its present site. There is no other district in any part of this city or in its suburbs where the hospital could be more advantageously placed and none where a more healthy site could be found. But the situation of St Bartholomew's is further of importance to its medical school, and we may be pardoned for thinking that this is also a matter of material public interest. For many years past St. Bartholomew's has been not only one of the most important hospitals in England but also the largest school of medicine. In this way the benefits of the hospital are not restricted to its numerous patients but are spread over Great Britain and its colonies. For the past 20 years an annual average of 600 students have studied at St. Bartholomew's and nearly one in every eight medical men in England can lay claim to the distinction of having learnt medicine and surgery there. The interests of the hospital and of its school are one and removal to some remote district would not only destroy the school but would also by so doing completely alter the whole character of the institution itself.

Many other reasons might very easily be adduced in support of the appeal for sufficient funds both to maintain St. Bartholomew's in its present position and also to make it one of the most complete and modern of English hospitals of which the City of London might well be proud But we have said enough to show the public that the present appeal is made in the best interests of the poor of London and we know that many thousands of our fellow citizens will now and in after years reap the benefits of those buildings which money alone can supply.

THE PROPOSAL TO PROHIBIT MEDICAL PRACTITIONERS FROM DISPENSING.

To the Editors of The Lancet.

Sirs,—I have read with interest your article entitled "The Medical Profession and the Dispensing of Medicines" in The Lancet of Jan. 23rd, p 242 It is to me a sign of hopeful augury as indicating the drift of opinion, at all events among the later generation of practitioners, that the discussion of this subject should have been found among the agenda of the British Medical Association. In your article, after quoting the clause of the Draft Medical Act Amendment Bill you plead for greater precision of the terms employed. Precision in law is certainly desirable but I would venture the opinion that in the explanatory details which follow the clause in question the work of definition has been overdone. No one surely would for a moment think of describing as a dispensing practitioner, in the ordinary sense of that term, a medical officer on shipboard or on military service compelled for the nonce to administer drugs to the sick in his charge. Still less, if possible, is the the term applicable to one who, in an emergency, finds it needful to administer a remedy. To treat as a pharmaceutical dispenser the physician who administered tuberculin, or, for that matter, the antitoxin diphtheriæ, to his patient would be, as you rightly suggest, to render homage to absurdity. It appears to me that all that the clause is intended to effect is the prohibition of the routine and business like assumption of the duties proper to the pharmaceutist pure and simple by the medical practitioner. The proposed rule would, in fact, extend to licensees under the Medical Acts the prohibition imposed in this connexion by the Royal College of Physicians of London upon its Members and the Royal College of Surgeons of England upon its Fellows and the penalty in case of disobedience would logically be that which is allotted to a breach of professional contract. The wisdom of imposing a penalty at the present stage is open to question. I think such a step would be premature. It must be borne in mind that the dispensing of drugs enjoys among the general practitioners of England a sanction of long standing. It is not to be expected that a change which requires its total extinction is to be brought about by a legislative stroke of the pen and enforced by the imposition of a heavy fine. Such reasonable time as may be considered adequate to a reconstruction of arrangements on the new basis must in justice be allowed to precede any attempt at absolute prohibition. It is nevertheless, I consider, quite within the right of the General Medical Council to announce its disapproval of dispensing as a regular adjunct of medical practice with a view to promote its spontaneous disappearance, and such an announcement should meet with general approval. In the meantime it would probably be best to leave in abeyance the consideration of more decisive measures.

I regret, Sirs, to have to express a difference of opinion with regard to certain of the conclusions arrived at in your article. You suggest that a non-dispensing system is incompatible with practice in country districts and in the poorer quarters of large towns. Experience is, of course, our best guide to a settlement of this question, but it is not without significance that we have already learned much from this source, both in this country and on the continent, which does not tend to support your contention. Otherwise, how are we to account for the fact that in France, Germany, and other European countries, even in Scotland, where the population is distinctly less wealthy than in England, prescribing, not dispensing, is the rule alike in towns and in many, if not in most, of the country districts. It is not to be supposed that a dispensing druggist will expect a poor man always to pay at the same rate as the well-to-do. The practitioner does not do this nor can the druggist. Again, it is asserted that with the disappearance of the dispensing practitioner, the prescribing druggist will flourish more than ever. Wherefore? The medical man who now supplants him in his means of livelihood will then provide him with greatly increased means of earning it. Is it not then the interest of the druggist to send patients to the medical man and is it not rather his interest in the present day to retaliate upon his rival dispenser of a higher qualification? I know from personal experience that druggists do continue to send patients unsolicited and without suggestion to the prescribing practitioner, doubtless with an eye to legitimate business The advantages which would accrue from a general adoption of the prescribing system are neither small nor few. The practitioner when released from what is to him the routine drudgery of making up his medicines will have more time to spend on the proper and sufficiently responsible duties of his profession. Being able to do more his ideal of work will be raised and the quality of that work will be improved to his own advantage and that of others, and there can be no question that he will also rise with it in public estimation The dispensing druggist, receiving a stimulus of opportunity hitherto denied to him, will not continue to be, as now he too often is found to be, unstocked with many of the requisites of medical treatment, and he will be met with in districts which have hitherto failed to support both him and a practitioner who is in effect an *alter ego*. Who can reasonably doubt that the population at large will be the ultimate gainer by the addition to its resources and its convenience which these wide-reaching improvements must entail. Nothing, however, is to be gained by rushing through a reform of this kind and I have no desire to see this question finally settled without full and adequate discussion. Precipitate action is more likely to defeat than to further its object. At the same time I can only view with satisfaction the fact that this subject has at last been brought prominently before the eyes of the medical profession, so that it may have some prospect of effective treatment on an extended scale. I believe that the result of critical inquiry will be to further the development of prescribing practice and to prove that a system which has been found to work satisfactorily in other countries is equally suited to the requirements of the English people.

I am, Sirs, yours faithfully,

Green Lanes, N., Jan. 26th, 1904. B. G. Morison.

To the Editors of The Lancet

Sirs,—The medical practitioner has frequently been indebted to you for championing his cause, and never more so than at the present moment when by your editorial remarks and the insertion of Dr J. Oliver's letter you have drawn attention to the grievous wrong which it is proposed to inflict upon him. I should like, with your permission, to point out one monstrous result which would follow if the proposal to prohibit medical men from dispensing were to become law, and that is that the capital at present invested in dispensing practices, amounting in the aggregate to many thousands of pounds, would at the end of three years be represented by as many hundreds only or less. It is a matter of common knowledge that druggists repeat prescriptions again and again at the request of patients, and if the proposal were to become law one visit to the medical man would suffice in place of, it may be, nine or ten or more necessary under the present system. And it would be a vain hope to expect that the patient would make good the difference by paying an increased fee—indeed, it is more than probable that he would wish to pay less as there is a second fee to be paid to the druggist. After a while, also, the patient would go directly to the druggist without troubling his medical adviser and so save a fee which he would come to consider unnecessary. The inevitable result would be a big slump in dispensing practices and a corresponding loss in capital invested. It would be no argument to reply that a medical man has no vested right in a patient; the fact remains that under the present system he has such a right and it would be nothing less than wholesale robbery to deprive him of it without an attempt at compensation and to divert the money which should go into his pockets into the coffers of the chemist and druggist.

I should also like to add from many years' experience in one of the poorest districts in London that such a scheme would be quite impracticable in working class districts. The working man is the backbone of a great many practices in the larger towns and his 1*d.* a week club payment or the small surgery fee he pays includes his medicine. He certainly will never pay a fee to the medical man and a second fee to the druggist and the practitioner in such districts will be unable to exist. This would inevitably lead, as Dr. Oliver points out in his letter, to still greater overcrowding of the already overcrowded out-patient departments of our hospitals and charitable dispensaries, an evil which even now cries aloud for a remedy.

I am, Sirs, yours faithfully,

Oxford-terrace, W., Jan. 25th, 1904. W. F. GRANT.

To the Editors of THE LANCET.

SIRS,—Dr. James Oliver has, I think, very wisely drawn attention to this extraordinary idea of interfering with the liberty of medical men. That such a proposition should be advanced at a time [illegible] of the falsification [illegible] are so extensively at [illegible] not only extraordinary but astonishing.

The medical man is absolutely responsible that his patient should have the exact drug, of proper quality, of the prescribed dosage, and for the right period. Under existing conditions he delegates this grave responsibility to others and cannot be assured in many instances that these requirements are fulfilled. The present system has grown up owing to the complexity of dispensing, but if our pharmacopœia were brought up to the present-day standard the greater part of this difficulty would vanish. Instead of giving advertisement to the advertising proprietary medicine vendors the medical man with little trouble and great saving of time to himself and patient could avoid resort to these undesirable methods.

I believe that this delegation of responsibility has done much to lower the reputation of the profession in many ways [illegible] should be put in the hands of a patient" and that "no medicament should be supplied to a patient except on the direct responsibility of a medical man."

I am, Sirs, yours faithfully,

HENRY RAYNER, M.D. Aberd.

Queen Anne street, W., Jan. 23rd, 1904.

LONDON HOSPITALS AND CENTRAL CONTROL.

To the Editors of THE LANCET.

SIRS,—If you regard this subject of sufficient general interest to warrant you in giving me a little more space I should be glad to reply briefly to the letter of "Hospital Surgeon" in THE LANCET of Jan. 23rd, p. 254. He has, I think, confused my proposal for the establishment of a central board with proposals recently made by other writers on the same subject. I agree with "Hospital Surgeon" that any board composed of delegates appointed by the hospitals themselves would be as useless to control the hospitals as is the present Central Hospitals Council or as is the General Medical Council to control the examinational activity of the universities and colleges which appoint the majority of its members. The two policies which seem to have secured the chief support from recent writers on this subject are either to strengthen the existing council by adding to the number of hospitals represented upon it or to invoke State aid and with it State regulation. The first, I believe, will prove [illegible] egarded with great disfavour by a [illegible] istrators, whilst all practical men [illegible] to be carried out during the life- [illegible] ation. Meanwhile the establishment of central funds to collect money for the hospitals is making it more and more difficult for the hospitals themselves to obtain individual support and at the same time shows no prospect of making such local and individual support unnecessary. Is it too much to ask that these three collecting funds should intrust to a board appointed by themselves the distribution of a small proportion of their alms in accordance with a plan which would increase both the central and local contributions towards medical charities in London and would provide at once a measure of effective control? The size of the board appointed by the three funds is not material to the scheme. One delegate from each fund, if one member with adequate leisure and experience could be found in each committee, would suffice. But whatever its size —and we can trust to the common sense of the appointing committees not to make it too large for its work—this board would possess the power of the purse and should be able as an independent body to perform the important functions assigned by "Hospital Surgeon" to his proposed commission. If the County Council or any other municipal or State authority were disposed to adopt the proposal to give certain hospitals free rates or to contribute to certain hospitals in proportion to the sums collected by the hospitals themselves it would be possible for such authority to make this board its almoner.

I venture to explain my suggestion a little more fully because I believe that the central authority proposed fulfils in nearly every respect the requirements of the kind of board desired by "Hospital Surgeon" and in the hope that being more within the region of practical politics than a commission appointed by the State it may secure his powerful advocacy.—I am, Sirs, yours faithfully,

London, W., Jan. 23rd, 1904. LAURISTON E. SHAW.

IN WHAT DOES CANCER CONSIST?

To the Editors of THE LANCET.

SIRS,—Under the above heading you published a letter from me in your columns on August 25th 1888, p. 395. Researches carried out during the intervening 15 years have tended to confirm both positively and negatively the thesis there advanced. Pathologists are coming to look more and more to the natural history and tendencies of the cell and less and less to vegetal parasitism as affording a solution of the mystery of cancer. The thesis to which I allude was thus stated in my letter of August, 1888:—

> If, then, we believe that in her wildest vagaries of pathological neoplasm nature makes no jumps; if we recognise a transition [illegible] malign, [illegible] carci- [illegible] inflam- [illegible] factor [illegible] may [illegible] malig- [illegible] In the [illegible] nal cells [illegible] the other [illegible] ither to differentiate into tissue or to suppurate. They lack the influence which makes for organisation; their instincts are of the lowest—are amœboid, in fact. They possess the fecundity of cells unfitted for "colonial" life and share their vagabond propensities. Herein lie the factors of malignancy, the causes alike of the rapid growth and the infectivity of cancer. It may also be, as Dr. Creighton with acumen and felicity has put it, that these cells possess a veritable "seminal" influence; that is, by their contact they cause other cells to generate, and make the offspring like [illegible] possibly should [illegible] suspended

If it be inquired whence this influence is which makes for malignancy [illegible]

I am, Sirs, yours faithfully,

Albert-terrace, Regent's Park, Jan. 27th, 1904. W. J. COLLINS.

"MANUAL TREATMENT IN TYPHOID FEVER AND DIPHTHERIA."

To the Editors of THE LANCET.

SIRS,—I a[illegible] ur criticism on my book ("[illegible] Treatment") which appea[illegible] 100. I feel, however, called upon to reply to two of your remarks. You state that "We have our doubts as to the wisdom of 'heart shaking' and 'side shaking' in typhoid fever and diphtheria." I would like to point out that these manipulations are of a very gentle nature, in spite of what their name might imply to the uninitiated. I have found in cases of typhoid fever and diphtheria that these manipulations, far from causing embarrassment of the heart or other distressing symptoms, could reduce the pulse-rate, remove intermittences of the pulse, if such existed, and make the cardiac action stronger and more regular; dyspnœa could also be relieved by their means. Two of my colleagues who practise Kellgren's methods have had the same experience.

You also state that "Surely also to allow absolute freedom of diet to a patient suffering from typhoid fever is, to say the least of it, risky." The manipulations we apply to a patient suffering from typhoid fever have the effect of preventing stasis in the abdomen by removing venous congestion and by equalising the pressure in different parts of the abdominal cavity; also of promoting the powers of assimilation and excretion and raising the natural power of resistance of the body, including in all probability the intestine. It is also likely that the formation of the natural antitoxin is aided. It is just because we are enabled to do this that the diet of the patient need not, as a general rule, be restricted. I stated in my book that I have always in *fever cases which come under my care from the beginning of* their illness allowed perfect freedom as regards diet and that I have never had the slightest cause to regret this procedure. I should perhaps have added that in the event of my noticing any harmful results arising in consequence of this freedom as regards diet I should at once take steps to regulate the latter in order to prevent or to remove such symptoms.

I am, Sirs, yours faithfully,
EDGAR F. CYRIAX, M.D.
West Hampstead, N.W., Jan. 23rd, 1904.

THE RELATIONS OF THE GENERAL PRACTITIONER TO THE CONSULTANT.

To the Editors of THE LANCET.

SIRS,—*Re* your leading article in THE LANCET of Jan. 23rd, p. 239, on the Relations of the General Practitioner to the Consultant, do you not think that the name of the consultant referred to should be made known or, any way, that "F.R.C.S." should furnish it to medical men who might ask him for same? This is a consultant unworthy of our professional confidence. I have discussed the question with two of my medical brethren and that is our feeling in the matter. We regard the circumstance as a most painful one, too.

I am, Sirs, yours faithfully,
Jan. 25th, 1904. E. A. LUBBOCK.

⁂ We feel that "F.R.C.S." must decide as to the advisability of communicating the name of the consultant to correspondents.—ED. L.

THE CAUSES OF HIGH INFANTILE MORTALITY.

To the Editors of THE LANCET.

SIRS,—A short time ago you inserted a letter on this subject in which I suggested that one of the causes of high infantile mortality among poor people was the want of proper medical help in the early stages of illness. The tables that are appended to the letter which I now send certainly show that, as a general rule, in those town unions which give very little out relief the infantile mortality is higher than in those which give a fair amount of out-relief. (It should be understood that the term "out-relief" includes all medical relief given in connexion with the Poor-law outside the workhouse, &c.) I may add that I possess some other evidence tending in the same direction. Of course, high infantile mortality arises from a great variety of causes but I think the facts here stated make it well worth while for the sanitary authorities in every district where a high death-rate for children prevails to inquire whether the poorest class have sufficient facilities for obtaining medical relief for their children. In the following tables I have called a union "indoor" which treated more than half its legal poor by means of indoor relief and the other unions I have called "outdoor." Under the heading "Infantile Mortality" I have given the numbers of infants per 1000 births who die under one year of age from the Registrar-General's tables for the ten years 1881-90. The first table includes all the London unions and the second table relates to the six largest towns.

I am, Sirs, yours faithfully,
Jan. 23rd, 1904. J. THEODORE DODD.

CHLORETONE IN SEA-SICKNESS.

To the Editors of THE LANCET.

SIRS,—Your correspondent, Mr. John Dunlop, invi experiences from others of the use of chloretone in s sickness. I, too, first heard of this use of chloretone thro your correspondence columns and a trial I made of it, so as a single case goes, amply confirms the claims of this d to soothe vomiting of reflex causation In a family atte by me there is a little girl, now about 12 years of age, w has all her life been subject to "train sickness." If ever s travelled by train for more than a few miles she was inva ably prostrated by vomiting Devices of all kinds were tri and finally medicinal treatment, without any success, t only sure way of avoiding the sickness was to avoid a r way journey of any distance, and this she religiously di but twice in each year, when going to and from the se side in summer, the infliction had to be borne. Eve precaution would be taken, the stomach kept reasonably empty, the recumbent position at once assumed and maintained, medicines taken, &c., but on every occasion without exception the journey was rendered miserable to all and she herself was upset for several days. This year I provided her with chloretone in capsules, of which she took two five-grain doses before starting. For the first time in her experience the journey was performed quite comfortably, and this although the distance was considerably longer than had hitherto been attempted. On the return journey a similar dose produced equally happy results. I have always assumed that the action of chloretone in checking sickness is due to its anæsthetic effect on the mucous membrane of the stomach which soothes and lessens reflex irritability.

I am, Sirs, yours faithfully,
Bromsgrove, Worcestershire, Jan. 25th, 1904. CAMERON KIDD.

To the Editors of THE LANCET.

SIRS,—Mr. J. Dunlop asks in THE LANCET of Jan. 23rd p. 253, for your readers' experience of chloretone. I advised a lady who is always, whatever the weather, miserably sick on crossing the Channel to try the effects of a dose of ten grains. She tells me that the result was perfect both on going and returning. In another case of a patient, 40 years old, with mitral disease and a bad stomach a state of nausea was caused by the withdrawal of morphia to which he had been accustomed for four years. Thanks to chloretone this symptom was relieved entirely and the only (and what appeared at the time a serious) obstacle to the successful suppression of the morphia removed. When, with a view to morphia weaning, the alkaloid is decreased gradually according to my plan, there is not as a rule any trouble of this kind, but in the case of a patient with a bad stomach in whom such a symptom does occur I do not think anything, that is in these circumstances allowable, is as likely to be as efficacious as chloretone.

I am, Sirs, yours faithfully,
Paris, Jan. 25th, 1904. OSCAR JENNINGS.

A DISCLAIMER.

To the Editors of THE LANCET.

SIRS,—My attention has been drawn to the report of a case in the *Daily Telegraph* of Tuesday, Jan. 26th, in which, during his cross examination, the plaintiff, Dr. Williamson, stated that my fee for the removal of enlarged onsils and adenoid growths of the naso-pharynx was 25 guineas. May I be allowed to state that I have never asked for, nor received, so large a fee for that operation? I regret that such a statement should have been made without my knowledge or consent.—I am, Sirs, yours faithfully,

Jan. 27th, 1904. HERBERT TILLEY, F.R.C.S. Eng.

1) WHAT IS VERONAL? (2) THE DANGERS OF TABLETS.

To the Editors of THE LANCET.

SIRS,—An article entitled "A Case of Veronal Poisoning" appears in THE LANCET of Jan. 23rd, p. 223. The writer iquires as to the nature of this new hypnotic. It was ntroduced only a few months ago and is di-ethyl-malonylrea. Its chemical formula is $C_8H_{12}N_2O_3$. The dose is from ve to 15 grains, but personally I have found ten grains a sufficiently large dose in those cases in which I have preribed it. The literature of the drug is as yet somewhat anty, but the article by Berent in the *Therapeutische onatshefte* for June, 1903, and that by Trautmann in the *herapie der Gegenwart*, 1903, No. 10, are well worth erusal. Apparently the patient referred to had taken an verdose, hence the disastrous results. All hypnotics are angerous and medical men cannot be too careful in preribing them for their patients, and no druggist should peat such prescriptions unless with the consent of the escriber.

The article entitled "A Case of Acute Sulphonal Poisong" recalls to my mind a letter which I wrote you some me ago, and which you were good enough to publish, on e dangers of tabloids or tablets, which you will. Mr. ind tells how the patient under his care took three bottles of sulphonal tablets. This form of medication, as I have again and again pointed out, enables patients to prescribe for themselves. Why the profession is not alive to this fact I cannot tell. Surely it is an easy matter to prescribe powders, pills, or cachets. Or do they imagine that the druggist is unable to dispense prescriptions? Very soon, indeed, the druggist will be unable to do so simply from want of practice. We are yearly degenerating so far as the art of prescription writing is concerned. It is rapidly becoming a lost art and the reason is that we trust more and more to the manufacturing chemist rather than take the trouble to master the contents of the British Pharmacopœia. We are simply playing into the hands of those who care little whether their wares are advertised to the public or to the profession so long as they obtain a world-wide market. *Even many of those houses which state that they do not* advertise to the public do so by means of show-cases placed in a conspicuous position in druggists' shops.

Assuredly, medical men are fools not to see through all this gelatin coating. The genuine article is beneath it but the covering is so suited to their tastes that they reck little of the rest. If we would be richer in pocket and loftier in tone as a profession we must first sweep away all this trumpery and get back to the old-time powders and pills which, after all, are much more valued by the public than tons of tablets and elegant elixirs.

I am, Sirs, yours faithfully,
Edinburgh, Jan. 23rd, 1904 JAMES BURNET.

DEATH AND SUDDEN DEATH.

To the Editors of THE LANCET.

SIRS,—May I be allowed, on behalf of Dr. Brouardel and for the sake of accuracy and justice, to make a slight correction in the leading article on "The Death of Miss Hickman" which appeared in THE LANCET of Nov. 21st, 1903, p. 1443. You write: "The remains had evidently not been disturbed saved by marauding rodents and the agents of putrefaction which Brouardel has so aptly termed 'the labourers of death.'" The authorship of the term "labourers of death" ("travailleurs de la mort") is really due to the distinguished entomologist M. P. Mégnin. Dr. Brouardel quotes and adopts the expression in his work "Death and Sudden Death," translated by myself, and acknowledges M. Mégnin's claim in the following words (second edition, p. 75): "The observations of M. Mégnin, who has carefully studied the insects which prey on dead bodies and which he has picturesquely styled 'the labourers of death,'" &c. The term is to be found in M. Mégnin's work, "La Faune des Cadavres," from which the account of the processes of decomposition by insects in "Death and Sudden Death" is drawn.—I am, Sirs, yours faithfully,

F. LUCAS BENHAM, M.D., M.R.C.P. Lond.
Exeter, South Australia, Dec. 21st, 1903.

A REPUDIATION.

To the Editors of THE LANCET.

SIRS,—Our attention has been called to a report of police-court proceedings under the Merchandise Marks Act in respect of adulterated soda crystals supplied by a Messrs. Burgoyne and Co., and as we are commonly known in the trade and medical profession as Burgoyne and Co. we ask the favour of your kindly inserting this letter disclaiming any connexion with the house or proceedings in question. Thanking you in anticipation of your compliance with this request, We are, Sirs, yours faithfully,

BURGOYNE, BURBIDGES, AND CO.
Coleman-street, London, E.C., Jan. 21st, 1904.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Sanitary Neglect by Municipalities in Bengal: Further Supersession. — The Mulkowal Disaster. — The Plague Epidemic.

THE municipal commissioners of Nadia having made persistent default with regard to the sanitation of the town have been declared incompetent to perform their duties and have been superseded. This is the second case within a few months. It appears that there are no less than 825 well privies within the limits of the town and in consequence of this method of disposal of the excreta the water-supply is excessively polluted. Repeated inspections, reports, and admonitions failed to induce the commissioners to make any improvement. A serious condition exists in the low level of the town, causing it at times to be inundated. The taxation of the town is ridiculously low, being only about 7½*d* per head, and the people are well able to bear the additional tax which will now be imposed. There is no analysis given showing the exact state of the water, but it is reported as "so polluted as to be unfit for human consumption." The mortality of the town has been increasing year by year—viz., from 25·4 per 1000 in 1899 to 42·55 per 1000 in 1902 The so-called well privies are nothing less than holes dug in the ground and being so numerous it can readily be understood how polluted the soil must be. Moreover, as wells exist for the supply of water within the town area the danger is constant, especially as the soil is of sand. Being a place of pilgrimage also a severe outbreak of cholera might develop at any time. These evils have existed for several years and it is a-question whether the Government is not to blame for allowing such a scandal to continue so long. This case is another instance showing that the natives of India are totally unfitted for sanitary administration.

At last some negative information about the Mulkowal disaster has been given. The medical officer who inoculated the villagers of Mulkowal with the antiplague serum has been granted a certificate to the effect that he is exonerated from blame in connexion with the accident in November, 1902. It will be remembered that 19 persons died from tetanus following plague inoculation. The real facts of the disaster are still suppressed and consequently distrust is widespread and the benefits of inoculation cannot be urged until confidence is restored. At the time of the appointment of the commission of inquiry I expressed doubts as to its fitness, but whatever its report more harm has probably been done by suppressing it than would have occurred by making public its conclusions.

The plague mortality throughout India has had a temporary decline, 15,606 deaths being recorded for the week ending Dec. 26th, 1903, as against 17,304 for the preceding seven days. The decline appears to be entirely in the Bombay Presidency, as the other provinces show but little change. The figures for the week are: Bombay districts, 5656, as against 7579; United Provinces, 2522, against 2504; Central Provinces, 1547, against 1687; Bengal, 1377, against 1039; the Punjab, 1049, against 1066; Central India 1176, against 1175; and Bombay city, 65, against 57. Although plague has been quiescent in Bombay city and rife in the Mofussil the Government still persists in confining its plague inspections to railway passengers leaving the city and to persons leaving the city by the coast steamers, while those arriving from infected areas are permitted to enter the city unchallenged. This very act shows the inefficiency of railway inspection, because, notwithstanding the virulence of plague in the districts, Bombay city has been quiescent as regards plague for over six months.

Jan. 9th.

IRISH UNIVERSITY EDUCATION.

(From a Correspondent.)

There is no question which is exciting greater attention in Ireland at present than the extremely thorny problem of the settlement of university education; and, unfortunately, political and sectarian feeling has entered so largely into the discussion that it is well-nigh impossible to touch the subject in a journal which is concerned with the matter simply in its bearings on the medical profession.

Every true Irishman, irrespectively of his religion or politics, must admit that the present position of educational matters in his native country is indeed intolerable, if for no other reason than for the great uncertainty on two points: (1) Is fresh legislation on Irish university education about to be introduced? and (2) In what direction is this new legislation to go? We have had a Royal Commission on University Education in Ireland giving us several volumes full of contradictory evidence and with many suggested schemes all illustrating the truth of the proverb, "*Tot homines, quot sententiæ.*" Then quite recently, as reported in The Lancet, we have had rumours of a scheme to settle everything by the creation of a national university with three autonomous and coördinated colleges, a plan put forward first by Sir Antony MacDonnell, the Irish Under Secretary, and afterwards by Lord Dunraven. Indeed, almost every week the press gives us details of various schemes which are to bring peace and contentment to Ireland.

As a natural result of all this utter uncertainty many Irishmen are at present sending their sons outside that country to be educated. We know of numbers of young men who have of late gone to Oxford and Cambridge and, from a purely professional point of view, it is a remarkable fact that in the year 1903 there were attending the University of Edinburgh 677 students of medicine and of these 118 were from Ireland. If to this number we add those who attended the extramural medical schools in that city as well as those who stopped at Glasgow, it is probable that from 150 to 200 students went from Ireland to Scotland to pursue their medical studies, a proportion altogether unknown a few years ago. So long as the present state of affairs exists this, I fear, will continue unless statesmen will say definitely that they will make some changes in Irish university education or they will not. Constantly to be leading people to expect legislative measures is a profound mistake and a sign of very feeble statesmanship if really nothing is meant in the end to be done. In attempting to give any country a new measure of university education three factors naturally suggest themselves: (1) The projected legislation should strictly follow academic lines; (2) it should aim at satisfying all sections of the people who demand higher education; and (3) it should possess the elements of finality.

Can any such scheme be put forward for Ireland? I fear many will say that Irish university education is a Chinese puzzle and that its solution passes the wit of man. A statesman in dealing with such a question, so full of inherent difficulties, might ponder over several solutions. First, he might attempt a scheme of united education but unfortunately it is impossible in Ireland, as even in such a field as secular education people will not unite. He might, however, persevere with the scheme in the hope that with mutual toleration matters in the end would come right. Secondly, he might grant sectarian education that is like Mr. Balfour's proposal—have three universities, one for Roman Catholics, one for Episcopalians (Trinity College), and a third for Presbyterians—or he might advise that there should be only two universities, one for Irish Roman Catholics and the other for Irish Protestants, the latter being Trinity College, Queen's College, Belfast, and other affiliated institutions. Or, thirdly, in despair the statesman after full inquiry might decide to leave matters *in statu quo* and to do nothing. This apparently is what is about to take place at present, for at a meeting held in Belfast on, Jan. 22nd the Marquis of Londonderry, who presided, said: "There is no question whatever of the creation of a Roman Catholic university. Let me say once and for all—and you may take it from me—that during the existence of the present Government there will be no question whatever of the creation or foundation of a Roman Catholic university." This is the last official pronouncement on this question by a member of the Cabinet. It does not, however, preclude Lord Dunraven's scheme being brought forward either by the Government or by a private Member.

BIRMINGHAM.

(From our own Correspondent.)

Degeneration of the National Physique.

It is the custom for the lecturer on hygiene at the Midland Institute to deliver twice in each year a public lecture on some matter connected with the laws of health. The present lecturer is Mr. William Wright who is also a lecturer in the anatomical department of the University, and the subject of his recent popular lecture was that mentioned above. Mr. Wright advocated the formation of boys' brigades and cadet corps and also suggested that the German plan of allowing ten minutes or a quarter of an hour's play to every hour's work in school was one which might with advantage be imitated.

Health of the City.

It is also a custom for the chairman of the health committee to preside at these lectures and to make a statement in reference to the health of the city. Alderman Cook on this occasion referred to the exceedingly low death rate of the past year, 17·1 per 1000, the lowest in the city since any records have been kept. The number of cases of typhoid fever was small, 362 as against an average of 588 in the previous ten years. The number of deaths of young children from summer diarrhœa was 597 as against an average of 645 in the previous ten years. Small-pox threatened to become prevalent on three occasions but owing to the energetic measures adopted by the health committee it never got beyond control and was stamped out. Eight patients were at present in the hospital but the committee hoped that the city would soon be clear of the disease. Owing to the diminution in scarlet fever the committee had again been able to provide accommodation for cases of typhoid fever at the Yardley-road Hospital and 11 patients were now being treated there. The alderman concluded by stating that in his opinion 16 per 1000 was an ideal death-rate and it was pleasing to know that the rate in Birmingham was approaching that figure.

The Training of Imbecile Children.

A conference has recently been held between representatives of the Birmingham board of guardians and of the education committee with a view of coming to a conclusion as to the best method of dealing with idiot or imbecile children and feeble-minded girls who should be placed under permanent care. Mrs. Pinsent, chairman of the special schools subcommittee, explained fully the work which was being undertaken by the after-care subcommittee which tries to help the children from the special schools after the age of 16 years when they become emancipated from all control. It was found that there were a large number of cases for which there was no adequate provision and the only thing that could be done for them was to advise the parents to make application for assistance to the Poor-law authorities. The parents were, however, in many cases prejudiced against the Poor-law and preferred, as they said, "to battle on without its assistance." Various suggestions were made and discussed as to the treatment of such cases by the board and the question of the treatment of feeble-minded girls when they reached the age of 16 years was fully dealt with. Cases were cited showing that this was a very serious subject. The members of the conference felt that legislation was necessary in this particular direction, the representatives of the guardians pointing out that in this, as in other instances which had been discussed, they could only deal with each case upon its merits. They also expressed their sympathy with the work which was being done and promised to give every assistance in their power to the after-care subcommittee in its work.

Midland Counties Home for Incurables.

The Earl of Denbigh presided over the annual meeting of this institution which has recently been held The receipts for the year had amounted to £6249, as compared with £5082 in the previous 12 months. Mr. Best's legacy of £2000 had been placed to the endowment fund which was still small and which only produced about one-tenth of the annual income. The average number of inmates during the year had been 87, as compared with 83 in the preceding year, and the number of pensioners had been raised to 29.

Antivivisectionist Pronouncement by a Bishop.

One is accustomed to hear extraordinary statements made upon antivivisectionist platforms but perhaps the most extraordinary which has ever come under my notice is that which the *Birmingham Daily Gazette* reports as having been made by Bishop Mitchinson, Master of Pembroke College, Oxford, at an antivivisectionist meeting held at Cheltenham recently. The attitude towards science and the acquisition of new knowledge which this speech reveals is one which one can hardly credit as existing at the present day. But the speech requires no comment. The bishop said that the [illegible] had a tremendous business [illegible] rt of the country. How was [illegible] ling against their cause to be [illegible] ere not cruel or callous. He [illegible] had all gone mad upon that [illegible] Oxford they were as "mad as a March hare" upon it and the sooner they were shut up in an asylum the better it would be for learning. They had actually been put to the necessity of offering "research" degrees the qualification for which was to have done what he should have thought it the part of any wise man not to do—write a book. They had it at every turn and it was not only amongst scientific men they found it. It was the same with classical men; they were wild about getting research somehow or other into the different examinations. The one great step towards salvation was to set their youngsters to research. It constituted amongst literary people a mania, and first of all it was fostered by academic clamour. The bulk of modern literature also had something to do with "finding out something fresh" and it was the same in theology. Everybody was trying to find and course a new hare. If one person found a queer thing in an animal everybody else had to find out two queer things, and they were never happy unless in finding some "mare's nest." He did not think all this a mark of intellectual progress; it was far too selfish. His lordship also regarded the lessened hold of religion and the "hide-bound, cynical body worship" as two other causes making against antivivisection. The scare for our own skins was largely due to the medical profession whose attitude on the vivisection question would, he was afraid, bring about a split between the soul doctor and the body doctor—had, in fact, already done so in some cases.

Electric Tramway Accident at Dudley.

An extraordinary accident and one of a character most alarming to the public occurred a few days ago at Dudley. A cart laden with iron and drawn by three horses was being driven up a road in the town where there are overhead wires and on account of the muddiness of the surface the cart was kept upon the paved tramway track. When about halfway up Castle-hill the driver noticed a flash coming from the tram-rails, immediately after which the leading horse swerved, or, as the driver imagined, was drawn against one of the iron pillars carrying the wires. The driver jumped down and taking hold of one of the horses sustained a shock which caused him to stagger. Almost simultaneously a blue flame was seen to spring from the iron pole and run along the draught chains of the cart. All three horses then fell to the ground as if struck by lightning and smoke was seen ascending from the portions of their bodies which the chains had touched. The driver of the cart was not seriously injured but all the horses were killed instantaneously. Moreover, at the points where their bodies had been touched by the chains there were deep burns, in some places penetrating to a depth of an inch. It was at first thought that an overhead wire had broken but when the state of affairs came to be looked into it was found that the accident arose from a defective insulator. This had been presumably burned through. At any rate, the damage had rendered the supporting pole "live" to the electric current and the condition of the horses shows that the current at the time must have been very powerful.

Prosecution of a Jam-Maker.

The city authorities recently summoned a local maker of jam for having on his premises several casks of fruit pulp for sale or for preparation for sale which were unfit for human consumption. When the inspector visited the premises the proprietor informed him that he made jam of various kinds from fruit pulp, sugar, and glucose; and grape jelly from grape pulp Rejected jams were re-mixed with fresh mixing, were reboiled and sold again. For sweetening purposes he said that he had used the refuse of boiled sweets of various kinds and as a result a quantity of the jam had been rejected. The inspector on his first visit found a number of casks containing gooseberry pulp in a state of decomposition, also bottles containing decomposed fruit. On his second visit these had been marked "Not to be used." The medical officer of health in his evidence stated that he had examimed the pulp and found it to be decomposed and to contain pieces of fungus. In answer to an inquiry from one of the magistrates he said that the effect upon those who ate jam made from this pulp would probably have been to produce gastric disturbance, possibly sickness, not much more than that, but that the result would certainly have been conducive to the spread of disease. The defence was that the proprietor had not sent for an inspector because he thought that if he had done so he would have been punished for having the pulp, although he had made it known himself by calling for inspection. It was also urged that the barrels had been labelled prior to the first visit of the inspector but that the labels had been washed off by rain. The bench, after retiring to consider the case, said that they found the offence proved and, regarding it of a grave nature, considered it their duty to impose the maximum penalty of £20 and costs or in default a month's imprisonment.

Jan. 23rd.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

"*Doctors and Friendly Societies.*"

IN the course of an address delivered at a meeting of Oddfellows in Hulme on Jan. 23rd Mr. W. J. Galloway, M.P., made some remarks on the relation between friendly societies and the medical profession which may perhaps excite criticism. So long as the present relations exist there will be no objection to the statement that "the interests of the societies were so interwoven with those of the great medical profession that it was essentially necessary good feeling should exist between the two." But when, as in his next sentence, he says "he sympathised with the view of the friendly societies that if a doctor entered into a contract to visit its members for a certain sum of money it was absurd of him to say he would only visit such members as earned only a certain wage," he raises debatable questions. He said further: "The question of wages had nothing whatever to do with belonging to a friendly society and indeed the latter welcomed all who would agree to pay the stipulated amount of subscription." It is quite true that if a man makes a contract he is bound to carry it out, but if anyone, however wealthy he may be, is welcomed as a member of a friendly society and as such claims the services of the medical man it will be necessary for medical men to consider whether such contracts are conducive either to their self-respect or to their material welfare. With many the result of such consideration would probably be that it was not desirable to take such contracts. Mr. Galloway went on to comment adversely on "certain doctors who formed societies and ran them as kinds of unlimited companies. They caught a certain number of people who would subscribe so much a week and for that they undertook to visit them whenever they were ill," and went on to say that it "very often happened that a doctor had a great many more patients than he could properly attend to" and that even when it was not so "it had unfortunately been proved that he had not given that care and attention that their cases required." These general accusations are easy to make and it would be well if Mr. Galloway would take the trouble to hear the medical man's view before endorsing the one-sided statements that have no doubt been made to him. The whole question of the medical treatment of those who are above the rank of paupers and below those who are sufficiently well-to-do to come under the category of "private patients" is fraught with difficulties. There are many objections to the "club system" as it is ordinarily understood. On the part of the members it leads to a sense of proprietorship as regards the medical officer and to scant courtesy, not agreeable to anyone with the feelings of an educated gentleman. The system of contracting to be kept in health is said to work well among the Chinese but it does not as a rule attract the Western mind and the unlimited private companies that excite Mr. Galloway's wrath are not popular with the majority of our profession, although it is quite possible, no doubt, that the medical man may run one with the integrity that Mr. Galloway desires the medical profession to maintain. He appears to think "it does not seem difficult to find some solution of the question which would protect the interests of the friendly societies and also those of the medical profession." He may possibly, therefore, find an opportunity of making useful suggestions if the "Bill to be introduced into Parliament for the better regulation of the medical profession" comes under discussion. But he must bear in mind that though long suffering the profession may become tired of being "sweated."

New Small-pox Hospital.

Application has been made to the Local Government Board on behalf of the Ashton and Stalybridge borough councils and the district councils of Hurst, Andenshaw, and Limehurst to form themselves into a joint small-pox hospital board to maintain a hospital at Hartshead Farm, which has an area of 41 acres. At the inquiry held at Ashton-under-Lyne Dr. Wheaton, the inspector, suggested that the mayors of Stalybridge and Ashton should be ex-officio members of the board. This was objected to by the various representatives but the difficulty was got over by all assenting to the chairman of the board of guardians being nominated an ex-officio member. Mr. W. H. Hughes of Ashton stated that at the beginning of the year there patients in the present unsuitable small-pox hos Ashton and 170 cases had been treated since the e broke out. It was agreed that the designation sh "Ashton and District Joint Small-pox Hospital." H will it be before such hospitals will be reminde disease once prevalent but now almost forgotten, leper houses which are still to be found in various the country?

Brandy and British Brandy.

A good deal is said just now about whisky bein adulterated with grain spirit and it seems that th are similarly cheated with regard to brandy, of wh reputed parent, or rather grand-parent, is the grape, is really made up of "spirit distilled from potato root, or something of that sort," with an infin modicum of French brandy. A grocer of Lower B was fined £10 and costs on Jan. 20th for stuff of this kind as Martell's Three Star Brand defendant said that it was ordered as ordinary and sold as such. It will be well, therefore, order "ordinary brandy." But he also said been sold to him as Martell's brandy, bottled by firm, and that the Manchester agent of that f since told him that an action had been bro Martell's against the printers of the label. The n Jan. 21st, the magistrates at Church were occupie similar case where the so called brandy was flavour or potato spirit. The chairman said it was evide custom of the trade to sell "British brandy," abou the public knew very little and were deceived and protected. For similar offences two other publica Oswaldtwistle were also fined. It is clear, therefo this nasty injurious stuff is sold very largely. If possible it would be better to stop its production fine the publicans who in some cases may be the deceived.

The late Mr. William Crosby, M.R.C.S. Eng., L of Salford.

Yesterday the funeral took place of one of the old most respected of the general practitioners of Salfo W. Crosby. He qualified as Member of the Royal of Surgeons of England and Licentiate of the Apoth Hall in 1847 and was 78 years old at the time death. His funeral was largely attended by of the profession, including Dr. Maguire of and by some of the principal inhabitants of By his knowledge of his profession and by his kindness he had long had a very extensive not limited to the Salford side of the Irwell. But his own calling he was well known for his great k knowledge of music and, like another of our Man medical men, he was an accomplished organist. F years he was a constant attender of Hallé's concerts refined features, of a somewhat Georgian type not fre seen in these days, were very familiar to the audienc leaves a widow and a wide circle of friends to deplo loss.

Jan 26th.

WALES AND WESTERN COUNTIES NO

(FROM OUR OWN CORRESPONDENTS.)

Administration of the Midwives Act in Cardiff.

AT a meeting of the Cardiff division of the Medical Association held in Cardiff on Jan. 21st the officer of health of the borough (Dr. E. Walford) *résumé* of the Midwives Act, 1902, and made reference to its local application The Cardiff corpo which is the local supervising authority under the A delegated the whole of its powers and duties to the committee and has appointed the medical officer of the executive officer, adding to his staff an add woman inspector who has had some training as a nur present she undertakes all the clerical work connecte the administration of the Act and later will car a certain amount of supervision and inspection response to public notices issued by the corpo 60 or 70 women applied for forms of application central board for certificates. Nearly all these applic were made on the ground that those applying were a acting as midwives, very few on the ground of holding any kind of certificate. Dr. Walford stated that he feared that the supervising authority would have some difficulty in making the former class of women carry out the rules of the central board in a satisfactory manner. Some are unable even to read or to write, while others have a most elementary knowledge of these arts and would be quite incapable of keeping the records and registers of cases and case books which are required by the board. Rule No. 17, which provides that a midwife must in certain specified circumstances decline to attend a patient alone and must advise that a medical practitioner must be sent for, met with some criticism at the hands of Dr. Walford and other members of the division. It was pointed out that the midwife can only advise the attendance of a medical man; there is no power to enforce his attendance nor is there any provision for paying him a fee. In view of these circumstances which might at any time be responsible for disastrous results it was decided to ask the Cardiff corporation to discuss the matter with a deputation appointed by members of the division in order, if possible, to arrive at some means of overcoming the difficulty.

Medical Acts Amendment Bill.

Clause 34 of the Medical Acts Amendment Bill, which has been drafted by the medico-political committee of the British Medical Association, met with a great deal of adverse criticism at the same meeting of the Cardiff division of the Association. The clause provides for the disclosure of the identity of a practitioner by requiring him to place his full name outside the premises in which he practises. Dr. T. Wallace and others considered that the price which general practitioners were asked to pay for the suppression of unqualified practice was too great and they thought that it was unnecessary to affix the name of an assistant or of a locum-tenent outside his place of residence. Ultimately a motion was carried (though not unanimously) approving of the clause with a recommendation for exemption to be made in the case of a locum-tenent or deputy holding office for two months or less and permanently in the case of all charitable institutions.

Instruction to a Bearer Corps in Infirmary Wards.

A suggestion has been made to the board of management of the Cardiff Infirmary by the officers of the Welsh volunteer bearer corps that members of the corps should be allowed to attend the male wards of the infirmary for the purpose of gaining experience in the dressing of surgical cases. It is proposed that each member of the corps should have two weeks' instruction in each year under the supervision, not of the surgeons, but of the ward sisters. With suitable restrictions there does not appear to be any reason why the nursing committee of the infirmary which has the matter under consideration should not comply with the suggestion. The members of the bearer corps could not fail to benefit by the instruction they would receive and the good work done by the institution would be much more widely known and appreciated than it is at present by the working classes of the town.

Vagrancy and Labour Colonies.

The court of quarter sessions of the Lindsey division of Lincolnshire has recently issued a very exhaustive report based upon an account of the Belgian labour colonies submitted by Mr. H J. Torr, J.P., and Major R A. Marriott, the governor of the prison at Lincoln. This report of the Lincolnshire justices was considered on Jan. 23rd by a subcommittee appointed by the Glamorganshire court of quarter sessions when a motion was unanimously adopted expressing the opinion that the vagrancy question required instant attention and recommending that the Government should be asked to appoint a commission to consider the best method of grappling with it. It is stated that in the Cardiff union alone the number of tramps dealt with in 1903 was 5500, an increase of 4400 over the number recorded in 1900. The Bridgend guardians have convened a conference of representatives of Glamorganshire boards to consider the establishment of a labour colony for the county.

University College, Bristol.

The fifth annual dinner of the University College Colston Society was held in the large hall of the College on Jan. 21st. Mr. Henry Hobhouse presided and the principal speakers were Sir John Gorst, who was the guest of the evening, and the President of Magdalen College, Oxford (Mr. T. H. Warren). Several references were made to the prospect of the College ultimately developing into a university. The financial statement showed that during the past year the sum of £387 had been raised by the society and this will be devoted towards the completion of the buildings of University College.

(FROM OUR OWN CORRESPONDENTS.)

The Rectorial Address at the University of Edinburgh: Rowdy Behaviour of the Students.

THE Lord Rector of the University of Edinburgh, Sir Robert Finlay, M P., appeared on Thursday, Jan. 21st, in the McEwan Hall to deliver the address which is expected from the person honoured by election to this high position. The chair was occupied by the Chancellor of the University, the Right Hon. A. J. Balfour, and he was supported and surrounded by much of the intellect of Edinburgh. The hall was crowded by those who were fortunate enough to have got tickets and by the students. The hour before the meeting was devoted to a students' concert. It was noisy and boisterous and the atmosphere did not augur well for the more serious ceremonial which was to follow. Even the Prime Minister's presence had no deterrent effect—only a few of the words he uttered in introducing the Lord Rector were audible. Sir Robert Finlay stood for nearly an hour before this great hall full of people and it is doubtful if 60 words were audible during the hour. There was a perfect pandemonium of noise of every conceivable description The students behaved in a way that has made Edinburgh thoroughly ashamed of them and the University is metaphorically gnashing its teeth. The scene recalled those of a quarter of a century ago before the days of the Students Representative Council. That body must have either lost its power or it did not anticipate what happened.

The Students' Representative Council and the Rectorial Address.

A special meeting of the Students' Representative Council was held on Jan. 26th to consider the conduct of the students on the occasion of the rectorial address and to take steps to prevent its recurrence. The following motion was adopted:—

1. That the Students' Representative Council, in its own name and [illegible]

continued and that [illegible]
of an hour or 20 [illegible]
meeting commence. [illegible]
to such gatherings it might be desirable that each professor
a day before such meetings should point out to his students
that the honour of the University on such occasions is very
largely in their keeping and that the public naturally judge the
whole institution by their condu [illegible]
members to resign his seat on [illegible]

vestige of any authority [illegible] in unseemly fancy costume.
person who accompanied him in unseemly fancy costume.

At the same meeting a letter was read from Sir Willliam Turner conveying a communication from the Principal and Deans committee on the same subject as follows:—

DEAR SIRS,—At a meeting of the Principal and Deans committee [illegible] connect New York with Brooklyn, between the Brooklyn Bridge and the lately opened Williamsburg structure. According to the *New York Herald* the most disastrous of all building operations in which it was found necessary to sink caissons was the New York East River gas tunnel where the men were at one stage working at a depth of 120 feet, under an air pressure of 52 pounds to the square inch, in addition to the normal atmospheric pressure of about 15 pounds. In the sinking of the caissons for the new Manhattan Bridge a depth of 92 feet has been reached, with an air pressure of 42½ pounds. There will be, however, no increase in the depth or in the air pressure. Dr. Andrew H. Smith of New York, the best-known authority on caisson disease in the United States, is of the opinion that a hospital should be established wherever caisson work is in progress, as a quick return to the conditions which induced the disease is, he deems, the best and nearly the only remedy for it. He therefore suggests that a chamber should be constructed in which a cot containing the patient could be placed and to which the compressed air could be admitted through a pipe connected with the caisson. After abatement of the symptoms the pressure should be very slowly reduced, as much as several hours being occupied in the process. Dr. Smith's advice will probably at once be acted upon.

Pneumonia in New York.

364 deaths occurred in New York from pneumonia for the week ending Jan. 9th, 143 more than recorded from the same cause for the corresponding week in 1903. 1635 deaths resulted from all causes in the week ending Jan. 9th of this year and of all the diseases which made up this large total pneumonia claimed by far the largest number of victims. Dr. William H. Guilfoy, registrar of records in the New York Department of Health, stated that of the 364 abovementioned deaths from pneumonia 239 were due to lobar pneumonia and 125 to broncho-pneumonia. New York is also undergoing an epidemic of measles; 800 cases were reported for the week ending Jan. 9th and there were also 189 deaths. This fact will largely account for the prevalence of broncho-pneumonia, while influenza and the extremely cold weather recently experienced in New York will account for the many cases of, and fatalities from, lobar pneumonia.

Treatment of Cancer by Radium in New York: Remarkable Cases.

Dr. William James Morton, professor of electro-therapeutics at the New York Post-graduate Medical School, delivered a lecture on Radium at a meeting of the Technology Club held in New York on the evening of Jan. 13th. Dr. Morton stated that he was treating a number of patients for cancer and that by means of radium he had effected three cures. The lecturer described the treatment of patients internally as giving them doses of liquid sunshine and bathing the diseased parts with rays of the sun condensed into liquid form and liberated by the action of radium. Dr. Morton went on to say that certain solutions, such as quinine, asculin, and orcin, when exposed to the action of radium become fluorescent and give off the violet and ultra-violet light of the solar spectrum. If the patient takes one of these solutions and lets it become absorbed by the blood and blood-vessels the application of the x rays or radio-active rays to the diseased tissues will liberate the violet rays in the solution and give the tissues what is equivalent to a bath in sunshine. This actinic stimulus stirs up the sluggish system to the work of rebuilding healthy and normal tissues, but, like other kinds of stimulus, it ceases to be beneficial when given in too great quantities. So far as the cure of cases of cancer by means of radium reported by Dr. Morton is concerned, he stated that several medical men of good standing had examined the patients and pronounced the cures complete.

Jan. 16th.

Obituary.

JOSEPH RABUTEAU WELLAND, M.D. DUB.,

LIEUTENANT, R.A.M.C.

THE news of the death of Lieutenant Welland at the battle of Jidballi on Jan. 11th was received with profound regret by his many friends. The deceased officer was born on Sept. 19th, 1878, and so was little more than 25 years of age when his death occurred. He was educated at Rossal and entered Trinity College, Dublin, in 1895 where he speedily became known as a persevering student of [illegible] turn of mind, always desirous of [illegible] ings of his text-books or his professors. At Steevens's Hospital where he was a resident in 1898, he was continually experimenting with drugs upon himself; just as at school, when he was learning chemistry, he would conduct experiments in his study by himself, no explosions—and they occurred—deterring him from finishing his research to his own satisfaction. He took his B.A. degree at the University of Dublin in 1899 and in the following year he was admitted M.B., B.Ch. B.A.O. In June, 1901, he joined the Royal Army Medical Corps and at the beginning of the next year he was ordered out to Somaliland where he was attached to the King' African Rifles. In April, 1903, he was invalided home and graduated M.D. in June of that year. In the Novembe following he again went out to Somaliland where he receive his death-wound at the post of duty, for the telegram relating to the battle of Jidballi seem to indicate that h fell speared while attending to the wounded.

Lieutenant Welland took a keen interest in boating and the Dublin Boat Clubs have sustained a serious loss by his death. In the Michaelmas of 1899 he won the "Junio Pairs." The following year he was chosen stroke and on the advice of R. C. Lehmann was transferred to the stroking o the senior crew for the Henley Regatta and he acquitte himself in this position in a manner which gained for hi the reputation of being the finest stroke seen in the clu for a decade. He stroked the college eight against th Pennsylvania crew which came over to England in 1901 t row for the Grand Challenge Cup at Henley and whilst o leave in 1903 he stroked the Lady Elizabeth eight—a post graduate Dublin crew—at the Boyne, University, Coleraine and Waterford Regattas.

GEORGE EDMUND LEGGE PEARSE, F.R.C.S. ENG., L.S.A.

WE regret to announce the death of Mr. G. E. Legge Pears which took place at his residence, Homefield, Merton Surrey, on Jan. 13th. Born in 1843, he was educated a Westminster School and subsequently entered as a medica student at Westminster Hospital, where he distinguishe himself, taking the Chadwick prize besides several clas prizes. After qualifying in 1864 as a Member of the Roya College of Surgeons of England, he spent two years at th Westminster Hospital, first as house physician and then a house surgeon, and later went to Manchester and becam senior house surgeon to the Royal Infirmary there. Returnin to London, he passed the final examination for the Fellow ship of his College and was appointed demonstrator o anatomy at Westminster Hospital Medical School, afterward becoming assistant surgeon and lecturer in surgery. H retired from active work about four years ago in consequenc of ill-health. He was a Fellow of the Royal Microscopica Society, a Fellow of the Zoological Society, and a Member o the Pathological Society. He was also a contributor to the medical press.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men ar announced:—Dr. Vasili Afanasieff, formerly lecturer o pathological anatomy in the Military Medical Academy, St. Petersburg.—Dr. Diego Coco, formerly *privat-docent* o internal pathology in Naples.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held in January the following candidate passed in the subjects indicated:—

Surgery.—R. S. Dollard, Royal College of Surgeons in Ireland and Westminster Hospital; P. Elias (Sections I. and II.), Amsterdam B. C. Ghosh (Section II.), Cambridge; F. W. Higgs (Sections I and II.), St. George's Hospital; and W. G. Kinton (Section I) and J. W. Watson (Section II.), Manchester.

Medicine.—W. V. Braddon (Sections I. and II.), Cambridge and Man chester; F. H. Hand (Section II.) and J. D. Keir (Section II. St. Mary's Hospital; W. G. Kinton (Section I.) Manchester; E. B. Price (Sections I. and II.), Birmingham; A. Rogers (Section II Cardiff and St. Mary's Hospital; A. Turner (Sections I. and II Charing Cross Hospital; and S. Zweiback Section I), Konigsberg

Forensic Medicine.—F. H. Hand, St. Mary's Hospital; W. G. Kinto Manchester; and A. Turner, Charing Cross Hospital.

Midwifery—H. Archer Leeds, C H J Fagan St George's Hospital W S Lewis, Birmingham and P B Whittington London Hospital

The diploma of the Society was granted to the following candidates entitling them to practise medicine surgery and midwifery —W V Braddon R S Dollard P Elias B C Ghosh J D Keir, W S Lewis and A Turner

TRINITY COLLEGE, DUBLIN —At examinations held in Hilary term the following candidates were successful —

PREVIOUS MEDICAL EXAMINATION

Anatomy and Institutes of Medicine—William G Harnett William C MacFetridge Joseph H Elliott and Robert E Dunn

Physics and Chemistry William F Casey, William F Samuels and Hercules J Knox

Botany and Zoology—James C C Hogan, Rupert Magill Robert L Lee Denis J Stokes Alexander K Cosgrave, John H Morton, John A L Hahn and William F Casey

MEDICAL MAGISTRATE —Mr George Philip Francis, L R C S Edin , L A H Dub , of Brecon, has been placed upon the commission of the peace for Breconshire

CENTENARIANS —Mrs Brembridge of Sidmouth, Devon, celebrated her 103rd birthday on Jan 21st She is the widow of the late Mr R Brembridge, Member of Parliament for Barnstaple, at which town she was born in 1801 —Mr Henry Wilkinson who died recently at Newby Wiske near Northallerton, celebrated his 100th birthday on Oct 23rd, 1903. On this occasion the local members of the Wesleyan body, to which he belonged, held special services and presented him with a sum of money He had eight children, of whom only one (now aged 75 years) is living

LITERARY INTELLIGENCE —Messrs. Wright and Co of Bristol have in the press a small work written by Dr W G Sutherland entitled "Dispensing Made Easy, with Numerous Formulæ and Practical Hints to Secure Simplicity, Accuracy, and Economy " It is designed specially for the dispensing medical practitioner and is the result of observations made while the writer was acting as locum tenent in over 100 different practices in England and Wales —Mr Alban Doran, after having played a prominent part in establishing the *Journal of Obstetrics and Gynæcology of the British Empire*, has resigned the editorship of that periodical Dr T W Eden has been appointed to fill his place

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN, WATERLOO ROAD, S E —The great Royal Opera House ball on behalf of the above hospital will take place on Tuesday next Feb 2nd We understand that all grand tier boxes have long since been disposed of and that two supper tables and one second tier box only are left unsold Large dinner parties for this ball have been

lds, and Miss Harmsworth
can be ascertained, is the
sed world and has already

relieved over a million patients On this account alone it deserves all possible assistance in raising the £50 000 required for rebuilding

LECTURES ON MEDICAL JURISPRUDENCE —On Jan 21st the second of a course of lectures on medical jurisprudence was delivered by Dr F J Waldo, coroner for the City of London, at the Old Hall, Lincoln's Inn The lecturer dealt with "Live Birth in Relation to Civil and Criminal Law," a subject of great importance to lawyers The consideration of live birth, he said, was naturally divided into two classes—namely, those which affected either civil cases of inheritance or criminal cases of infanticide In both the evidence that established the fact of live birth was identical The medical view of live birth differed from the legal The medical man demanded proof of the establishment of circulation and of respiration even when the child had not been born into the world In this way crying was one of the most satisfactory proofs of respiration and hence, to the medical mind of live birth The law, on the other hand, was content with the faintest sign of vitality, provided the child was fully born into the world, as establishing the fact of live birth The tremor of a muscle or the quiver of an eyelid might be sufficient evidence of live birth from the legal point of view The positive signs of live birth, as laid down by Casper were next discussed and the crucial point of viability or the capacity of a child to survive birth was treated at some length The remaining lectures of the course will be delivered on subsequent Thursdays They deal with death in its medico legal relations, insanity, and poisons

THE WEARING OF MEDALS BY EX-CIVIL SURGEONS.

To the Editors of THE LANCET.

SIRS,—In reply to Ex-Civil Surgeon's queries *re* his South African medal, he can with good taste wear it when in evening dress but it should be in miniature form with ribbon attached The War Office some 16 years ago sanctioned the wearing of medals by officers when in evening dress, and the custom is followed by many officers, from the Commander-in-Chief downwards, when attending public dinners, &c.

I am, Sirs, yours faithfully,
Jan. 25th, 1904. I. M. D.

THE HICKMAN REWARDS.

THE £100 reward offered by Mr. Hickman and the £100 offered by the board of the Royal Free Hospital for the discovery of the late Miss S. F. Hickman have, we are authorised to state, now been paid. The money has been applied as follows—viz.: £5 paid to the lad, H. W Mackinney, who first gave information to the police, and £5 to the boy's father for clothing and necessaries. The balance of £190 will be invested by the Mayor and Vicar of Richmond in Government stock, in trust, as to £90 for the boy Mackinney, and £50 each for Fennell and Watkins, the two boys who were with Mackinney in the plantation. The interest of these sums is to be applied for the benefit of the boys until they attain the age of 21 years and the principal then is to be paid to them.

BIRD "PRESERVING."

IN THE LANCET of Jan. 16th, p. 203, we recorded the humanity and the interest in ornithology displayed by Mr. E. *Symonds*, a game keeper, who saw a wax-wing and did not shoot it. But the usual idiot with a gun has turned up and Mr. E. Kay Robinson writes to the *Times* of Jan. 26th that according to the press of Jan. 21st "a wax-wing has been shot near Beccles." It is difficult to speak politely of the person who committed this act but let us hope that he was simply an ignoramus, not a collector.

A CASE OF ACUTE TRAUMATIC CHOLECYSTITIS.

To the Editors of THE LANCET.

SIRS,—In the case of acute traumatic cholecystitis reported by Dr. F. J. Smith and Mr. C. W. Mansell Moullin in THE LANCET of Jan. 23rd, p. 220, might not the injury have been caused by the man falling with his right arm under him? The internal condyle of the humerus in that position is opposite the gall-bladder.

I am, Sirs, yours faithfully,
F. F. JONES, M.R.C.S. Eng., L.S.A.
Twerton-on-Avon, Bath, Jan. 26th, 1904.

A WARNING TO MEDICAL MEN APPLYING FOR SHIPS' SURGEONCIES.

To the Editors of THE LANCET.

SIRS,—I obtained an appointment as ship's surgeon through an agent who introduced me to the shipping firm's superintendent and they both told me that the voyage would be for six months. I unfortunately signed the ship's articles without putting in a special clause as I trusted to the statements made to me at the time of engagement. I was kept at sea for nearly a year and I might have been detained for two years but luckily the steamer was ordered back to England. I was refused permission to leave at the end of six months by the captain on any other condition than that I found a substitute, which was impossible. I was informed by the shipping firm when I returned that they entirely ignored any responsibility in the matter and that as I had signed the ship's articles they were entitled to my services for two years at £6 a month, unless the steamer returned within that time, and that the contract made with the agent did not concern them. I write this to warn others who may be similarly placed not to sign the ship's articles without inserting an extra clause if necessary.

I am, Sirs, yours faithfully,
Jan. 23rd, 1904. LATE SHIP'S SURGEON.

◆

Scrutator.—1. The patient is apparently "in such circumstances as to require relief for his proper care" and must therefore be dealt with as a pauper by the relieving officer under Section 14 (2) of the Lunacy Act, 1890. 2. The justice before whom the alleged lunatic is brought may call in any registered medical practitioner to examine such alleged lunatic and is not bound by any contract between the guardians and their medical officer. In practice, however, justices are accustomed tacitly to sanction contracts of this kind. Unless, therefore, there are special circumstances which would lead the justice to ignore the medical officer of the district "Scrutator" is not likely to be asked to certify. 3. The justice's order is in Form 12 of the second schedule of the Act. 4. Children "being of a sufficient ability" are liable for the maintenance of a parent. The extent of the claim made is at the discretion of the guardians.

A. B. C.—We consider that the proposer should be told of his condition. He will be to some extent prepared for the bad news by the fact that the insurance company, upon our correspondent's report, will certainly either refuse his life or only accept him upon very high rates. We think that the proposer might be told in general terms that the result of the investigation is to show him to be not a first-class life, while he should be advised to consult his own medical man with regard to particulars. These particulars could be communicated by "A. B. C." in confidence to the proposer's own medical man.

W. J. B.—Radio-active rays are not in the ordinary sense visible to the eye. Their existence must be made manifest by a fluorescent substance. The gleaming of the cat's eye presumably acts as a warning to the prey.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses o their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should b marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To th Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1903, which was completed with the issue of Dec. 26th, were given in THE LANCET of Jan. 2nd, 1904.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1903 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.			
One Year	£1	12	6
Six Months	0	16	3
Three Months	0	8	2

TO THE COLONIES AND ABROAD.			
One Year	£1	14	8
Six Months	0	17	4
Three Months	0	8	8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not o affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittan

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies o should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manag Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addres

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Adv tisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31 Rue Bapts, Asnières, Paris.

A Lecture

ON

THE PHYSIOLOGICAL ACTION AND ANTIDOTES OF SNAKE VENOMS WITH A PRACTICAL METHOD OF TREATMENT OF SNAKE BITES.[1]

Delivered in the Physiological Laboratory of the University of London on June 9th, 1903,

BY LEONARD ROGERS, M.D., M.R.C.P. LOND.,
CAPTAIN, INDIAN MEDICAL SERVICE.

DURING the last few months the physiological actions of a number of snake poisons, representing every class of these poisonous reptiles, have been investigated by me in this laboratory in continuation of previous work in India, the main results of which I propose to bring before you to-day, illustrating the different points as far as possible by my own experience but referring to previous work wherever advisable.

In some of the earlier investigations on snake venoms no very essential differences were detected in the action of the various classes, but the large amount of work which has been carried out in recent years has shown that they may be broadly divided into two classes: first, the colubrines—of which the cobra is the best worked out—acting mainly by paralysing the respiratory centre in the medulla and the motor end plates of the phrenic nerves, more especially combined with a much less important action on the blood; and, secondly, the viperine class, which have hitherto been thought to act mainly on the blood, producing intravascular clotting as in Russell's viper of India, or loss of coagulability and hæmorrhages as in the rattlesnake of America. I shall hope to show you presently that a still more important and constant action of the viperine class is the production of a paralysis of the central vaso-motor centre in the medulla, just as the colubrine class paralyse the respiratory functions of this part of the nervous system, a factor which has been hitherto largely overlooked except for a reference to it by Weir Mitchell and Reichart in their classical work on the rattlesnake. It will simplify matters if I first direct your attention to a table in which I have summarised the actions of each of the four classes of snake poisons, illustrating them by examples of species which I have myself investigated (Table I.).

You will see from the table that the venoms having the colubrine action characterise the sea snakes (which I have carefully investigated during the last two years), the hamadryad or king cobra, and the two kinds of krait. The viperine poisons include the viperidæ, represented by the daboia Russellii of India and the African puff adder; and the crotalidæ or pit vipers (which differ from the former in having a depression in the scales beneath the eye the function of which is not known) which are represented by the rattlesnakes of America and the trimensurus, or tree viper of India. A study of the venoms of these species will serve to illustrate all the important points of this extensive subject, a brief summary of which is all that I can attempt to-day. With regard to the chemical nature I will only mention that the venoms all contain actively poisonous albumoses (the peptones of the older literature) and that the viperine ones are coagulated and rendered inert at a lower temperature than are the colubrine ones. You see in the table a very marked difference between the colubrine and the viperine poisons, especially in their actions on the nervous system. Nevertheless, the difference is not absolute; there are connecting links between the two classes and I shall show you presently that the venom of the bungarus fasciatus, or banded krait, is of mixed colubrine and viperine action, as was found to be the case by C. J. Martin in the Australian colubrine snake the pseudechis porphyacus. Further, according to Weir Mitchell and Reichart and to Flexner, some of the pit vipers of the Western Hemisphere contain varying proportions of the colubrine element acting by paralysing the vaso-motor and respiratory centre, so that in certain species mixtures in varying proportions of the two active nerve poisons are present. Again, the relatively slight action of some at least of the colubrine poisons in reducing the coagulability of the blood and in lowering the blood pressure may well be minor degrees of the much more marked similar effects brought about by the viperine poisons. There is, then, a gradation by means of connecting links between the main colubrine and viperine divisions—a point the great interest of which will become clearer after I have described the actions of the different venoms.

TABLE I.—GIVING A SUMMARY OF THE ACTIONS OF THE DIFFERENT CLASSES OF SNAKE VENOMS.

		Species.	On the nervous system.	On the blood.			On the arteries.
				Hæmolysis.	Coagulation.	Hæmorrhages.	
Colubrine venoms.	Hydrophidæ (sea snakes).	1. Enhydrina Bengalensis.	Paralysis of respiration and end plates.	Very slight.	Slightly reduced.	*Nil.*	—
	Colubridæ.	2. Cobra.	"	Very marked.	Much reduced.	"	Vaso-constriction.
		3. Hamadryad (king cobra).	"	Very slight.	—	"	—
		4. Bungarus cœruleus (common krait).	"	Fairly marked.	—	"	—
		5. Bungarus fasciatus (banded krait).	Ditto, a viperine action.	Very slight.	—	"	—
Viperine venoms.	Viperidæ.	1. Daboia Russellii.	Paralysis of vaso-motor centre.	Marked.	Marked thrombosis and loss of coagulability.	Very slight.	Vaso-constriction.
		2. African puff adder.	"	"	"	Marked.	—
	Crotalidæ (pit vipers).	3. Trimensurus.	"	"	Ditto, but thrombosis less marked.	Fairly marked.	—
		4. Rattlesnake.	"	"	No general thrombosis; loss of coagulability.	Very marked.	—

ACTION OF COLUBRINE VENOMS ON THE NERVOUS SYSTEM.

The best known of the colubrine venoms is that of the cobra, the physiological action of which was first carefully studied by Brunton and Fayrer some 30 years ago. They showed that its primary action was a paralysis of the respiratory centre and of the motor end plates, especially of the phrenic nerves; they also ascertained the important fact that by means of artificial respiration the circulation could be kept going for many hours after natural breathing had finally stopped as a result of the poison. Their researches were confirmed by Ragotzi and by Vincent Richards and Wall in India, although attempts by an Indian commission, including Vincent Richards, failed to obtain complete recovery in animals by artificial respiration. More recently Calmette's serum has been made by injecting horses with increasing doses of a mixture of venoms, mainly consisting of cobra poison, for many months and it has an undoubted specific action against cobra venom. It has therefore become a matter of practical importance to ascertain whether the physiological action of other colubrine venoms (including that of the hydrophidæ which are morphologically colubrines adapted to an aquatic existence) is the same as that of the cobra and if so whether Calmette's serum is also effective against them and in what doses, especially in view of the fact that C. J. Martin has found that it had only a very slight and practically unimportant antidotal action against the Australian colubrine snakes.

---

[1] A grant in aid of the research work on which this lecture is mainly based was received from the Royal Society, by whom the original full papers have been published. Some work done since the delivery of the lecture has been added.

HYDROPHIDÆ OR SEA SNAKES.

Enhydrina Bengalensis.—This is the commonest and most deadly of the sea snakes which swarm round the coasts of India and not infrequently cause loss of life among fishermen. I have collected venom from four out of the six genera met with in Indian seas and found them all to produce death with typical colubrine symptoms, so that the enhydrina will serve to illustrate the action of the whole class. The symptoms of poisoning by comparatively small doses are as follows. After a long latent period, which in the case of very small doses may last several hours, the animal begins to show signs of sleepiness, closing the eyes now and then and nodding its head. After a while it sits down and begins to show signs of commencing muscular weakness, for when aroused movements are only carried out with difficulty. It will now be found that the animal is breathing both more quickly and deeply than normal, but before long the number of respirations becomes decreased in frequency while still laboured in character. The paralysis increases until the animal cannot stand or raise its head, the respirations become slower and slower, finally violent respiratory convulsions set in, the animal rolls over on its side, and the breathing finally ceases, the heart continuing to beat for a few minutes longer. After death the blood is found to be dark, but it clots very firmly when placed in a test tube and after a time exudes a nearly clear serum. Stimulation of the phrenic nerves with the secondary coil of faradic current produces no contraction of the diaphragm, but the muscle responds to direct stimulation. A typical curara effect is thus present and I find that the nerve trunks are not affected, as the direct application of strong solutions of the venom does not alter the negative variation of the current of injury. The sciatic and other nerves may or may not show this complete motor end plate paralysis, it being most marked after large doses of the venom.

The symptoms which I have just described are precisely similar to those produced by cobra venom, of which respiratory paralysis is the characteristic effect. For their closer study I have taken simultaneous tracings of the respirations by means of a Sandstöm's recorder and of the carotid blood pressure by a Gad's manometer and will now show you some slides illustrating the results. The sequence of events you will see is the same in each, the time in which they appear varying inversely with the dose administered. The first change noted is a steady slowing down of the respiration, the amplitude of which is also decreased until breathing ceases, by which time the blood pressure has begun to rise above the normal as a result of commencing asphyxia, only to fall rapidly soon after respiration has finally ceased. This asphyxial rise of pressure is most evident after small doses in which respiratory convulsions are marked. In every case the respiration failed before the circulation and motor end plate paralysis was found post mortem affecting the phrenic nerves and after the larger doses also the sciatics, &c. In order to study the time relationship between the paralysis of the respiratory centre and of the phrenics an experiment was performed in which this nerve was exposed in the neck, and the minimal faradic current, which would produce a contraction of the diaphragm when applied to the nerve, was noted. It was found that almost complete failure of respiration occurred before the phrenics showed any weakening, so that the primary action of the poison is clearly on the respiratory centre in the medulla. Next I tried the effect of artificial respiration in maintaining the circulation after cessation of natural breathing. The process was begun when the respirations had almost ceased at the commencement of the usual terminal asphyxial rise of pressure. The result was that the rise was counteracted and the circulation was steadily maintained as long as the inflation of the lungs was carried on only to rise once more on leaving it off. This sequence of events occurred repeatedly and even when respiratory convulsions were allowed to begin renewed artificial respiration both lowered the excessive blood pressure and stopped the convulsions. Here once more we find similar results to those obtained by Brunton and Fayrer with cobra venom.

There are a few other points of interest concerning the sea-snake venoms which I made out while in India. The quantity of venom obtained from them was very small, the average amount got from an enhydrina four or five fee in length being 0·010 gramme only, but it makes up for thi by its great toxicity, which in the case of birds I found to be ten times as great weight for weight as that of cobra venom, being by far the most potent snake venom I know of. On comparing its action on fish (which these sea snakes live on) with that of cobra venom I found that while 50 times as much cobra venom per kilogramme was required to kill fish as was necessary to kill birds, in the case of the enhydrina poison only ten times as much was necessary, while the venom of some other sea snakes killed fish in only very slightly larger doses than they killed birds—a remarkable adaptation of the poison of the sea snakes to the needs of their environment. Again, some harmless snakes withstood 100 times the fatal dose for a fish and 1000 times that for a bird. Further, I found that the enhydrina poison resembled tetanus toxin in that small quantities of it may be fixed and rendered inert by being mixed for some time at blood heat with fresh brain matter of a highly susceptible animal, so that the great differences I have just mentioned in the susceptibility of different classes of animals to the venom may possibly be due to varying affinities of their nervous systems for the poisons.

INDIAN POISONOUS COLUBRINES.

Hamadryad or king cobra.—This is the largest and most deadly snake in India, if not in the world, but is fortunately rare. In a few experiments made by Fayrer many years ago it was not observed to differ in its effects from cobra venom, but I am not aware that its physiological action has hitherto been closely examined. I will show you some tracings illustrating its action on the respiration and circulation. In the first experiment five milligrammes per kilogramme administered intravenously paralysed the respiration in one and a half minutes, while the blood pressure began to fail half a minute later. In the second, with one-fifth of the former dose, you see that there occurred a temporary increase in the number and amplitude of the respirations, followed by the usual steady failure and cessation after ten minutes. In both cases the phrenics were completely paralysed after death, but stimulation at regular intervals in the first experiment showed that their paralysis had not commenced until after failure of the respiratory centre. In the third tracing you see the effect of artificial respiration, showing that the circulation could be kept up for a long time after respiration had finally ceased by this means, just as in cobra and enhydrina poisoning. Hamadryad venom, then, also resembles in its action cobra venom.

Bungarus cœruleus or common krait.—This is a small, very widely distributed poisonous snake of the colubrine class. Thanks to the kindness of Dr. V. W. Shaw in giving me a small quantity of its venom I have been able to get a tracing of its action on the respiration and circulation and to do some other experiments with it. The tracing presents the characters typical of a colubrine poison. The respiration ceased in four and a half minutes, while the blood pressure shows the usual late asphyxial rise and the heart continues to beat for some minutes longer. After death the end plates of the phrenics were weakened but not completely paralysed, this venom having apparently less action on them than that produced by the other colubrine poisons. In other experiments on small animals the symptoms were typically those of colubrine poisoning.

Bungarus fasciatus or the banded krait.—This snake is much larger than the common krait, yet it has been considered by Fayrer, Wall, and others to be less deadly than its smaller relative. Wall has also described a chronic form of poisoning by it, in which respect its effects differ from those of other colubrine snakes. I have performed a number of experiments with it which bring out these points more distinctly. In the first place weight for weight it is a very much weaker venom than the other colubrine poisons, for I found its lethal dose to be seven milligrammes per kilogramme in pigeons, or 14 times as weak as cobra venom, 22 times as weak as the common krait, and no less than 140 times as weak as the venom of the enhydrina (see Table III.). When small doses are injected into pigeons typical colubrine symptoms are produced, but with larger doses intravascular clotting may be found more especially in the portal system, just as I shall show you presently is typical of most of the viperine poisons. This venom, then, contains both the colubrine and the viperine elements. I shall return to this point in speaking of the antidotes to the colubrine poisons and will now show you tracings illustrating its action and exhibiting what I regard as points of exceptional interest. The first three experiments were carried out on rabbits the blood pressure of which is always rather low. In each of them the first effect of the poison was to cause a marked fall in blood pressure which was to a considerable extent recovered from after a short time. Then a steady failure both in frequency and amplitude of the respirations occurred (preceded in the case of the smallest dose of five milligrammes per kilogramme by a temporary increased rate). With the failure of respiration the usual asphyxial rise of blood pressure to above the original height took place and the heart continued to beat for several minutes after the cessation of the breathing. So far the effects were typically colubrine, but in one of these animals a small clot was found post mortem in the portal vein such as is commonly produced by a viperine poison, but never by a purely colubrine one. In the other two cases, however, there was no clotting to account for the temporary fall of blood pressure. *The next tracing from a cat injected with ten milligrammes per kilogramme* intravenously shows a still more marked primary fall of blood pressure accompanied by an immediate cessation of respiration, both of a very temporary nature, and this was followed by the usual steady respiratory failure of colubrine poisoning. In this case as soon as breathing finally ceased artificial respiration was started, but it had only a momentary effect in keeping up the circulation instead of a prolonged one, as in all purely colubrine arrests. In each instance the phrenics were found to be completely paralysed after death, and in one case of a dose of 20 milligrammes per kilogramme the sciatics were also similarly affected. The primary temporary fall of blood pressure and the failure of artificial respiration to avert the final circulatory failure after cessation of breathing are, then, peculiar to the poison of the banded krait among Indian colubrine snakes, while I shall show presently that these are characteristic features of viperine poisons, so they are doubtless due to the viperine element already pointed out. In order to test this further a lethal dose of venom was heated to 90° C. for half a minute, an application of heat which has a much greater effect on the viperine than on the colubrine element. The result was a much less marked primary fall of blood pressure and a much greater effect of artificial respiration in maintaining the circulation than in the last experiment; doubtless due to the elimination of most of the viperine action, thus confirming the presence of this element in the unheated natural poison.

ACTION OF COLUBRINE VENOMS ON THE BLOOD.

Hæmolytic action.—The very marked action of cobra venom in dissolving the red corpuscles of the blood has long been known and has been more especially studied by D. D. [illegible] named [illegible] the lc[illegible] action of all the colubrine poisons in Table I. by adding small measured quantities of blood to varying strengths of the venoms dissolv[illegible] counting the number of red [illegible] as well as in controls, and [illegible] Table II. gives the strengths required to produce complete, or very nearly complete, hæmolysis in 24 hours.

TABLE II.—*Hæmolytic Action of Colubrine Venoms.*

Snake.	Blood.	Strength of venom.	Complete hæmolysis.
Enhydrina	Human.	1 in 1,000	In 24 hours.
Cobra	,,	1 ,, 100,000	,,
Hamadryad	,,	1 ,, 1,000	,,
Common krait	,,	1 ,, 10,000	,,
Banded krait	,,	1 ,, 1,000	,,

It is evident from these figures that the cobra venom has an exceptionally powerful hæmolytic action compared with the other colubrine venoms. The common krait comes next to it, while that of the others is very slight indeed, especially in the case of the enhydrina venom, which relatively to its lethal power has only one-thousandth part of the hæmolytic action of cobra venom. Yet even in the case of the cobra, if the red corpuscles be counted before the administration of a lethal dose and again immediately after death, the decrease in their number is very far short of what would be required to produce a lethal effect, while in the case of the enhydrina I have not been able to detect any reduction in the number of the red corpuscles as a result of a minimal lethal dose. It is clear, then, that the hæmolytic action of the colubrine venoms as a class is of very slight importance compared with their action on the nervous system and that it is quite a negligible quantity in producing death, except perhaps in the case of cobra venom in very large doses.

Action on the coagulability of the blood.—Cobra venom when added in solution to blood prevents its clotting, as was shown by D. D. Cunningham. I have found that this action is possessed also in a lesser degree by enhydrina venom, for while a 1 in 200 solution of cobra venom permanently prevented the clotting of the blood, the same strength of enhydrina venom only prolonged the clotting time by a few minutes. This action in both cases is too slight to influence the mass of circulating blood of an animal in ordinary doses, *but it will be sufficient to render it fluid locally at the seat* of injection of the venom and so may materially increase the rapidity with which it will be absorbed through the open mouths of the small vessels severed by the fang, and in this way it probably plays an important part in producing the extremely rapid action of relatively very large doses of colubrine venoms.

ANTIDOTES TO COLUBRINE VENOMS.

The relative value of Calmette's serum against different Indian colubrine venoms.—We have learned that the physiological action of the venoms of the hydrophidæ and poisonous Indian colubrine snakes is identical with the exception of the added viperine element in the case of the banded krait. We now have to see if Calmette's serum has the same specific action against the others as it has against the cobra. To test this I have carried out a series of experiments with each of the colubrine venoms by mixing varying quantities of the same serum with an equal amount of the venoms (about ten times a lethal dose being employed) and injecting the mixtures after half an hour at room temperature (18° to 20° C.). The amount of serum required to neutralise a given quantity of serum in vitro was thus obtained and the results are shown in Table III. In column 1 is given the minimal lethal dose of each of the venoms per kilogramme weight, which, you see, varies so greatly that the differences can be explained only on the hypothesis that they contain widely different proportions of the active respiratory paralysing poison. If this is so, then an equal weight of enhydrina poison will contain ten times as much of the active toxin as does cobra venom, and the amount of serum required to neutralise ten milligrammes of the former must be divided by ten before we can compare the action of the serum against equal quantities of the active

principles of the two venoms. In this way the figures have been obtained showing the cubic centimetres of serum required to neutralise toxin equivalent to ten milligrammes of cobra venom. Two different varieties of cobra venom have been tested, the first being the common one, from which most of the antivenin is prepared; and you see that the antivenin acts better against this than against the rarer variety. Not far behind comes the closely related hamadryad, then the enhydrina (a sea snake), while its action against the krait is more feeble. In all of these some of the animals were saved by the serum from at least ten lethal doses of the venoms, but, on the other hand, no recovery took place from the venom of the banded krait, for, although the colubrine symptoms were neutralised by the larger doses of serum used, the animals died three or four days afterwards with symptoms of slow viperine poisoning—probably the chronic form described by Wall—thus confirming the conclusion I had previously come to that this venom is a mixture of the colubrine and viperine elements.

The fact that Calmette's serum has a definite specific action against all the above purely colubrine poisons, including one of the sea snakes, is an interesting and important one, but we have further to consider the doses which must be used. In column 4 of Table III. is entered the amount of serum required to neutralise one lethal dose of each venom for a man of 50 kilogrammes weight, about the average of natives of India, and you will see that the amounts are very large except in the case of the common cobra. Further, we must know how many lethal doses the different snakes eject at a single bite on an average, as well as the limits within which they vary, but even here the data available are incomplete and even contradictory. Thus, D. D. Cunningham, working in Calcutta, a home of the cobra, gives the average amount for this snake at 0·254 gramme, while Lamb quotes Calmette as placing the amount at *from* 0 030 to 0 045 gramme, or about one-sixth *to one-eighth* of Cunningham's figure. In the case of the enhydrina I obtained an average of 0·010 gramme, or about four lethal doses for a man, judging from its effects on birds and rabbits. In column 7 the amounts of serum required to neutralise in vitro the average amount ejected by different snakes is entered, the doubtful ones being placed in brackets, and it will be seen that the amounts are very large, while if injected after the venom they would be still larger. It is clear, then, that the serum must be made much stronger if it is to be relied on to save patients who have received full doses of any of these venoms. If sufficient is given to neutralise all but a little less than one lethal dose the patient would be saved, so that theoretically the dose of serum can be reduced by an amount equivalent to a little under one fatal dose, but in practice it could not be cut so fine, while it is advisable to prevent all symptoms by fully neutralising the whole of the venom received

In view of the conclusion just arrived at I think that wherever possible such serum as is available should be injected intravenously so as to obtain the fullest and most rapid action possible. In colubrine poisoning its use should never be neglected as we cannot know the dose injected by the snake and whether the serum available may not suffice to reduce it below a fatal dose, especially if combined with a method of destroying much of the venom locally, which I shall describe to you presently. I think also that it may be possible to obtain a more generally powerful antitoxin by using in its preparation a mixture of the different purely colubrine venoms. Artificial respiration may also be of great value in keeping the patient alive while medical aid or antivenine is being sent for; one case is on record where life appears to have been saved by this method of treatment.

Viperine Poisons.

I have already mentioned that hitherto the main action of the viperine poisons has been considered to be their effects on the blood but that my observations of the last few months have led me to the conclusion that the blood changes are altogether secondary in importance to the failure of circulation by paralysis of the vaso motor centre. It will then be most convenient in the case of these venoms first to consider their effects on the blood and to see if they are sufficiently constant and extensive to account for the symptoms and lethal effects observed and subsequently to deal with their action on the nervous system and with their antidotes.

Action on the Blood.

On the coagulability.—The first point I have to draw your attention to is the marked difference between the action on the blood of the daboia Russellii, a true viper, and of the rattlesnake, a pit viper, the two vipers which have been hitherto most carefully investigated. In the case of the daboia it was suggested by C. J. Martin and shown by Lamb that, in small animals at any rate, the most marked action is the production of intravascular clotting, causing rapid death with violent convulsions. On the other hand, Weir Mitchell and Reichart found that a total loss of clotting power of the blood accompanied by *hæmorrhages* was the essential feature of rattlesnake poisoning; they considered that it also had a marked action in paralysing respiration. Flexner, who has recently made a careful study of the blood changes caused by the rattlesnake, lays stress on the absence of intravascular clotting. This apparently opposite action is, however, largely a difference of degree, for when thrombosis is produced by daboia venom the remaining unclotted blood has usually entirely lost its coagulability, as in rattlesnake poisoning. D. D. Cunningham showed that if repeated small doses of daboia venom, each insufficient in itself to cause *death by thrombosis*, are injected subcutaneously, then no intravascular clotting takes place, but on the contrary the negative phase of reduced coagulability is produced as in rattlesnake poisoning. I have fully confirmed this important observation and have found further that rapid death from circulatory failure without any intravascular clotting can be readily and constantly produced by first giving small do either subcutaneously or intravenously, and after a t larger doses by either method of administration. T significance of these observations lies in the fact that in t case of such large animals as man intravascular clotting h not been found to occur, but only a loss of clotting a hæmorrhages.

That the difference between the action of daboia a rattlesnake venom on the blood is one of degree rather th of kind is confirmed by some results which I have obtain in the cases of the African puff adder (for the venom which I am indebted to Dr. J. W. W. Stephens) and of Indian representative of the rattlesnake—namely, trimensurus anamallensis (for which I am indebted to Dr. Dowson), the physiological action of which has not, so far I am aware, been previously investigated. The puff add venom, whether administered subcutaneously or intr venously, may cause intravascular clotting like the dabo but it is more easily prevented by a single small prelimina dose than in the case of daboia poison, and in that ca complete loss of coagulability alone results. Again, in t case of the trimensurus venom I have obtained still mo remarkable results, for in small doses intravenously loss coagulability without any thrombosis was produced, as the rattlesnake, while larger doses caused immediate int vascular clotting of a rapidly fatal nature, as in dabo poisoning. These differences evidently depend solely on t rapidity with which the poison enters the blood, a precisely parallel results are obtained when Wooldridge "tissue fibrinogens" are injected intravenously. It is clea then, that there is no essential difference in kind in t action of viperine poisons as a class on the coagulability the blood, but only a difference in the *amount* of t thrombosis-producing element in the different venom the daboia containing the largest proportion and pr ducing the most marked clotting, and the rattlesnake t least, while the puff adder and trimensurus are intermedia gradations between the two extremes.

Hæmorrhagic action.—The next most important action the viperine poisons on the blood is the production petechial hæmorrhages, more especially in the mesentery an other parts of the peritoneum, the peri- and endo-cardiu especially of the left ventricle, more rarely in the pleura, an *always at the seat of injection into the tissues.* Here, agai different degrees of the effect are produced by the variou venoms which I have investigated. They are far the mos marked in the case of the rattlesnake, while they are almos *absent in fairly rapid* poisoning by the daboia even wher there is no intravascular clotting. After intravenous injectio of a fatal dose of rattlesnake venom I have seen marke hæmorrhages at the end of 15 minutes, while when watchin the circulation in the mesentery the passage *of red* corpuscle into the tissues outside the vessels can *be seen* within a few minutes following the very marked vaso-*dilatation* of the portal system The pericardium may also contain a blood stained effusion within an hour of the injection of the poison. Flexner has recently attributed this phenomenon to a dissolution of the endothelial cells lining the vessels. On the other hand, in acute daboia poisoning with death from circulatory failure without any intravascular clotting such hæmorrhages are usually entirely absent, although I have occasionally seen slight petechiæ in the endocardium of the left ventricle similar to those occurring in rattlesnake poisoning. Here, again, I have found intermediate degrees in other vipers, for the puff adder venom, although this is a pure viper like the daboia, produces very marked petechial hæmorrhages only second in degree to those of the rattlesnake, while the trimensurus, although a pit viper, causes less marked hæmorrhages than the rattlesnake or the puff adder but greater in degree than those of the daboia, so that here again we have a regular gradation running through the viperine venoms, only the lesser degrees are not peculiar to the true vipers or the more severe ones to the pit vipers.

Hæmolytic action.—In all four of the vipers dealt with a fairly marked hæmolytic action was met with, for if the incoagulable blood obtained after death be allowed to stand in a test-tube for a day the corpuscles will sink and the serum remaining above will be found to be blood-stained. Lamb has studied this action and concludes that it is more marked in the body than in vitro, but in any case it is much less than that produced by cobra venom and it is certainly of very slight importance as a factor in the causation of death by these venoms, especially in the more rapidly fatal cases.

Will the blood changes account for the fatal symptoms?—I now come to the question whether these blood changes will satisfactorily account for the lethal effects of the viperine venoms. In the case of small animals bitten by a daboia or puff adder death is certainly commonly produced by intravascular clotting, but this is not so in the case of rattlesnake poisoning, or in man when affected by either class of viper. In such cases the further question arises: Will the secondary loss of coagulability of the blood accompanied by hæmorrhages fully account for death? That mere loss of clotting power will not be fatal unless it produces uncontrollable hæmorrhages is clear from what we know of hæmophiliacs. Further, cases have been recorded by Weir Mitchell and others in which animals injected with rattlesnake venom showed complete loss of clotting power for several days, accompanied by marked hæmorrhages, yet made a complete recovery, so that even persistent loss of coagulability is not necessarily fatal in these cases. More conclusive still is the fact that with all the four viperine venoms mentioned I was able repeatedly to produce death without any thrombosis and without anything more than a few petechial hæmorrhages, which could not have materially affected the vitality of the animals. Lastly, in one experiment with trimensurus venom the usual well-marked circulatory failure occurred, but after an hour very evident signs of recovery showed themselves and persisted. The animal was killed and the blood was found to be completely incoagulable and petechial hæmorrhages were present, so that recovery, for a time at any rate, was taking place in spite of the persistence of the blood changes produced by the venom. In the fairly rapid deaths without thrombosis, then, it is clear that there is some important factor present other than the blood changes, and our question must be answered in the negative and some more potent cause of death sought for. This we shall find in the circulatory changes already referred to.

ACTION ON THE CIRCULATION.

This has been studied by taking similar tracings to those I have already shown you in the case of the colubrine poisons. First, single lethal doses of daboia venom were injected intravenously and subcutaneously and the expected intravascular clotting followed a few seconds after the direct injection into the blood stream and some minutes after the subcutaneous injection of a much larger dose of the venom, the tracings showing a primary circulatory, quickly succeeded by a secondary respiratory, failure or just the reverse of what occurs in colubrine poisoning.

On reducing the dose a very different and unexpected result was obtained, for when 0·1 milligramme per kilogramme (one tenth of what produced immediate thrombosis) was given intravenously a primary steady fall of pressure occurred eight minutes after the injection, followed quickly by a secondary cessation of respiration and respiratory convulsions such as commonly appear just before death But instead of the heart quickly ceasing to beat the blood pressure rose again rapidly, well-marked Traube-Hering curves appeared, and slow breathing recommenced. A few minutes later the blood pressure suddenly declined once more, although the slow but well-marked pulse indicated that the heart was still beating strongly. On the recurrence of respiratory convulsions the pressure once more rose and Traube-Hering curves reappeared, this sequence of events being repeated no less than five times before the final fatal circulatory failure occurred. Post mortem there was absolutely no intravascular clotting found anywhere, nor were there any hæmorrhages, although the blood was quite incoagulable. Here, then, we have a primary circulatory failure of peculiar character produced by a very small intravenous dose of daboia venom without any intravascular clotting. At first I thought the peculiar curve I have just described might be explained by capillary clotting in the pulmonary circulation, the obstruction caused by which was overcome for a time by the pumping action of the respiratory convulsions. To test this hypothesis I transfused both saline solutions and the fluid blood always found after viperine poisoning through the pulmonary, portal, and systemic circulations from given heights in a series of cases of both daboia and rattlesnake poisoning without any naked-eye intravascular clotting and found that both fluids always passed through readily from a head of only from 30 to 40 millimetres, so that it was evident that there was no capillary obstruction due to clotting or other cause. I therefore proceeded to carry out a long series of experiments with the four varieties of viperine poisons already mentioned in order to ascertain the real nature of the lethal circulatory failure without clotting which was the one important factor which I found to be common to the action of all of them.

In the first place I established the fact that by first giving small doses of daboia venom, either intravenously or subcutaneously, to produce the negative phase of reduced or lost coagulability, followed by a further larger dose by either mode of injection, the primary circulatory failure without any intravascular clotting could always be induced, while it was still easier to get it with the puff adder venom. In the case of the rattlesnake it was always caused by a single lethal intravenous dose and also sometimes with trimensurus venom. This circulatory effect is, indeed, the only important symptom which is common to all four of these venoms; neither the thrombosis nor the hæmorrhages are produced by all of them and the hæmolytic action is of slight lethal importance. Secondly, on testing the effect of these venoms on the heart directly they were found to have no power to slow or to stop its action even in stronger solutions than those which produced circulatory failure when injected intravenously, so that the action of the venoms could not be explained by any direct action on the heart itself.

The remarkable Traube Hering curves, already mentioned, pointed to an action on the vaso-motor centre, so this point was next investigated in the following ways. Complete vaso-dilatation was produced in a dog by cutting across the spinal cord in the cervical region and the circulation was maintained by means of artificial respiration. On now injecting first a small and a few minutes later a large dose of daboia venom no sudden primary circulatory failure was produced, such as occurs in like circumstances in which vaso-dilatation has not previously been produced, while the continuation for some minutes of the pulse showed that the heart also was not paralysed. Again, when a very marked and persistent fall of blood pressure, without any thrombosis, has been produced by a viperine venom, then section of the spinal cord in the cervical region caused no further persistent fall of pressure, showing that complete vaso-dilatation had already been produced by the venom. This was confirmed by the fact that once the Traube-Hering curves (of vaso-motor origin due to the struggles of the affected centre to maintain the blood pressure) had disappeared and a persistent very low pressure had been produced by the venoms, then stimulation of the central end of the sciatic nerve with a strong faradic current failed to cause any rise of blood pressure, proving that the vaso motor centre had been completely paralysed by the venom. Once more the circulation in the mesentery or omentum was watched under the microscope and the portal vessels were seen to dilate very markedly coincidently with the primary fall in blood pressure. The rise of blood pressure on the occurrence of respiratory convulsions can also be readily explained by the mechanical aid afforded to the circulation by the contraction of the diaphragm and other muscles emptying the dilated portal and systemic vessels and driving the blood on to the empty heart and possibly assisted by stimulation of the failing vaso-motor centre by the venous blood produced by the previous cessation of respiration Lastly, I have been able to demonstrate the dilatation of the portal circulation coincidently with the fall in the general blood pressure by means of simultaneous tracings of the carotid pressure and of the variations in the volume of a loop of small intestine (the ends of which had been ligatured) placed in an oncometer connected with a recording apparatus. If the fall of general blood pressure was of cardiac origin the lever of the oncometer should fall simultaneously with the decrease of the carotid pressure, owing to less blood passing to the intestinal vessels as well as to the carotid artery, but you see from the tracings that with the fall in the carotid pressure the oncometer lever rises rapidly showing a very marked dilatation of the portal vessels and that this rise is already well marked by the time the carotid pressure begins to show itself. The only exceptions to this were when intravascular clotting occurred in the portal circulation, when both levers fell rapidly together. These experiments furnish final proof that the primary circulatory failure is due to vaso-dilatation, while I have already given you some evidence that this paralysis is of central origin. It is conceivable, however, that it might be partly due to a local action on the blood-vessels, especially in view of the undoubted action of some of these venoms in dissolving the lining cells of the small vessels and so causing hæmorrhages. In order to test this Dr. T. G. Brodie very kindly tried the effect of cobra and daboia venoms on the peripheral vessels cut off from the central nervous system, using his perfusion apparatus, and we found that both cobra venom in large doses and daboia venom in very small ones caused marked local vaso-constriction. It is clear, then, that the vaso-dilatation is purely of central origin, occurring in spite of a contrary local action on the blood-vessels.

We arrive, then, at the conclusion that the essential lethal factor of all the viperine venoms tried is the production of a paralysis of the central vaso-motor centre producing a primary circulatory failure, followed by a secondary respiratory failure, due to deficient supply of blood to the medulla.

I should also mention that none of the viperine venoms ever produce any paralysis of the motor end plates of the phrenics or other nerves.

ANTIDOTES TO VIPERINE POISONS.

Calmette's antivenine.—Calmette's serum has no efficiency against the viperine venoms, apparently because he heats for a short time the mixtures of venoms which he uses in its preparation and thus destroys, or very greatly weakens, the small proportion of viperine poison in the mixture. A few observations which I have made support the conclusion that the antivenine is useless against the vipers; its failure against the mixed venom of the banded krait already referred to points to the same conclusion.

Vaso-constricting drugs.—The discovery of the main lethal action common to all the viperine venoms dealt with naturally led me to try how far the primary circulatory failure due to vaso-motor paralysis can be counteracted by such drugs as have a powerful effect in contracting the peripheral vessels, the most important of which is suprarenal extract. I found that 0·1 to 0·5 cubic centimetre of a 1 in 1000 solution of adrenal chloride (Parke, Davis, and Co.) immediately sent up the blood pressure in cats poisoned by viperine venoms, but that if the vaso-motor centre was already completely paralysed (stimulation of the central end of the sciatic nerve no longer causing any rise in pressure), then the effect of the adrenal extract only lasted a few minutes. On the other hand, if there were still well-marked Traube-Hering curves present the effect was much more lasting and powerful. Nicotine, which was suggested to me by Sir Lauder Brunton, in doses of one milligramme for a cat, also had a similar effect in restoring the blood pressure and at the same time it powerfully stimulated the flagging respiratory centre, being superior to adrenal in this respect. Further, some increase of the blood pressure of considerable duration was obtained by means of pressure applied to the abdomen by a binder acting by partly emptying the portal vessels and bandaging the limbs might also assist in a similar way. As, moreover, the venoms of the vipers are much weaker weight for weight than the colubrine venoms (daboia being about ten times as weak as cobra venom) it is probable that the vipers do not often eject much more than one lethal dose for a man. Hence a larger proportion of borderland cases of viperine poisons may be expected to be met with than in the case of colubrine bites and the methods of maintaining the circulation just described may very possibly prove to be of value in saving the lives of some cases which not so treated might prove fatal, so that in the absence of any specific antidote to viperine poisons the above suggestions appear to be well worthy of consideration.

A SIMPLE AND PRACTICAL METHOD OF DESTROYING SNAKE VENOM IN THE BITTEN PART.

Lastly, I come to a practical method of treating any kind of snake poisoning which promises to be of great value in all cases seen early and which might be carried out by any intelligent person if a medical man was not at hand. I have shown you that Calmette's serum is not strong enough to prove efficient against full doses of colubrine venoms, while it is very seldom at hand when wanted and tends to lose its power in a hot climate. It is also useless for viper bites, while the methods I have described of counteracting the physiological effects on the circulation of the latter would not be likely to succeed when very full doses have been injected. If, however, most of the poison could be destroyed locally at the seat of its injection before much of it had gained access to the circulation, then the above metho might prove efficient in dealing with the comparatively sm amount of venom already in the system. Many attem have been made to find some substance which would destr the poison at the seat of injection, the best known of which permanganate of potassium, which Wynter Blyth first show will rapidly destroy the power of cobra venom when mi with it in vitro. But experiments by Brunton and Fay and others, in which strong solutions of this substance w injected at the seat of insertion of the poison, did not pro successful in averting the death of the animals. They ha however, recently suggested a more radical plan of using t salt—namely, first to place a ligature round the limb abo the seat of inoculation of the venom and then to make small incision through the place of injection and to rub pure crystals of the permanganate moistened with a litt fluid, with a view to neutralise as much as possible of t venom before it has had time to be absorbed into the circul tion. At their request I have carried out a preliminary seri of experiments to test this method of using the salt wi very promising results.

In the first place I set to work to find out if the pe manganate will destroy other venoms than that of the cob by mixing from 10 to 20 lethal doses with a fraction of cubic centimetre of a 10 per cent solution of permangana of potassium, enhydrina, bungarus fasciatus, rattlesnak African puff adder, and daboia venoms being tried. Th mixtures were injected into animals after from five to te minutes, with the result that none of them showed any sym ptoms of poisoning except one which had received a ve large dose of bungarus fasciatus venom mixed with less tha its own weight of the permanganate and in this case th animal lived longer than a control with less than one thir of the dose, so that most of the venom had been destroye locally in this instance. It is clear, then, that the salt wi destroy in vitro nearly its own weight of every class of snak venom. Next, rabbits and cats were chloroformed and injected with several times a fatal dose of cobra or daboi venom, a ligature was applied after half a minute, five, o 10 minutes, and the treatment described was carried out, th ligature being released immediately after its completion. I the case of the rabbits only very marked prolongation of life, as compared with the controls with the same doses, wa obtained, owing to these animals being found to be muc more susceptible to the venoms than cats, so that the dose injected into the rabbits were many times a lethal quantity In the case of the cats much more favourable results were obtained, only two out of 12 animals treated having died, one being the first case treated with cobra venom, while the other had received five times a fatal dose of daboia venom (a much larger dose than this snake could inject in the case of an adult man) and the ligature was not applied until after five minutes. On the other hand, recovery took place after 10 lethal doses of cobra venom treated after half a minute from five lethal doses after five minutes, and from three lethal doses after ten minutes; while with daboia venom animals were saved from five lethal doses after half a minute and from three lethal doses after five and ten minutes respectively. I also found that even 30 seconds after the injection of the venoms there was a local extravasation of blood-stained serum present which clearly indicated the position of the poison and the salt was rubbed in directly over this until the tissues were quite blackened. The amount of tissue thus destroyed was quite superficial, while the salt has antiseptic properties. I hope to have an opportunity of carrying out further experiments on my return to India very shortly with fresh venoms and to wait longer before ligaturing the limb so as to ascertain the exact limits of the value of this method. The rapid local effusion which I have just mentioned makes me think that after the first few seconds this pouring out of lymph will very materially retard the rapidity of the absorption of the venoms so that it is possible that even half an hour or more from the time of the bite a considerable proportion of the venom may still be unabsorbed at the site of its injection and so may still be destroyed by the treatment suggested, and it is obvious that if this can be done at any time before a fatal dose has entered the circulation life will be saved and in any case the chances of success with the other methods of treatment will be greatly enhanced. That the absorption of a subcutaneous injection of snake venoms is very slowly completed is shown by the fact that one milligramme per kilogramme of cobra venom in a cat will kill in a few minutes when injected intravenously, yet the same dose takes from 24 to 48 hours to cause death when injected subcutaneously. When a very large dose, such as 50 times a lethal amount, is injected subcutaneously into a dog's tail and this member is cut off inside the seat of injection within a few seconds the animal will still die, as shown by Fayrer years ago. The reason is that one fatal dose may be absorbed out of such a large quantity within a few seconds. In the case of man, however, such a relatively large dose can never be received, so that there is much longer time for action, how long can only be determined by further experiments on animals. Nevertheless, I think that the results I have given you are sufficient to warrant the use of this method in practice, especially as it is efficient against all kinds of snake venoms. At the suggestion of Sir Lauder Brunton an instrument has been made consisting of a lancet covered with a sheath, in a small space at the base of which permanganate crystals are kept, the whole being but one and a half inches in length, so that it can easily be carried in a corner of the waistcoat pocket always ready for instant use. This will shortly be sold at a very low figure so as to bring it within the reach of even the poorest classes in India and elsewhere.

In conclusion, I have to express my best thanks to Dr. A. W. Waller and to Dr. T. G. Brodie and Dr. N. H. Alcock for much very valuable advice and assistance in the course of my researches here.

Some Observations

ON

MEDICAL EXAMINATIONS FOR LIFE ASSURANCE.

Being the Presidential Address delivered before the Life Assurance Medical Officers' Association on Jan. 27th, 1904,

BY SIR DYCE DUCKWORTH, M.D. EDIN., LL.D.,

PRESIDENT OF THE ASSOCIATION; PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

GENTLEMEN,—The honour which you have conferred upon me in electing me to the presidency of this society is one which I fully appreciate and I can do no more than try during my term of office to emulate the efforts of the distinguished men who have preceded me here. It will not be contested that during the few years of the existence of this association the work already accomplished in it has fully justified the expectations of its originators and earned credit from all who have taken part in it. The association is truly representative of a large body in our profession which before our foundation was loosely, if at all, bound together and devoid of any means of conference. There was abundant experience at hand, all unrecorded and lost as time passed on, but there was no organised body of reapers to gather in the harvest of it. We are now engaged in utilising this experience for the benefit of the general public as well as for ourselves. We constitute no kind of trade union here but we bring the best traditions of our catholic profession to bear on all our relations with the public and the several bodies which we represent or act for. The results of our efforts here are, I repeat, for the general credit and benefit of the different life assurance associations which we serve, and they assuredly tend to more exact and uniform performance of our duties.

I have long been of the opinion that the habitual examination of lives for assurance purposes constitutes one of the most useful and thorough methods of training for the daily work of the clinical physician. Such work is a constant check upon mere routine Each case presents a new problem and requires the full appreciation of the personal factor which is so necessary, and, alas, not always observed, in practical medicine. It is a daily study in physiognomical diagnosis—a subject too little taught in our schools in these days. It tests and sharpens our wits in framing prognosis. Again, how great is the advantage of reviewing, as we often have to do, the perfectly normal and healthy bodies of our candidates. We have so constantly the frail and the abnormal before us that we do well to be often in face of the sound and robust to recall us to the recognition of healthy standards. And here I would make this further remark, that in our daily duties as physicians we are apt, as we gather experience, to think better of many of the frail and abnormal subjects that we encounter and to project for them a fairer forecast than is possible for the average actuary or insurance office director to do. We follow the progress of individuals who present defects and manifest here or there inadequacy of one or more organs of the body, and know how much can be done for them, how they may be protected from their untoward tendencies, and how much recuperation is to be hoped for. But while we sometimes feel perplexity from this source we are bound to have regard to the business side of the transaction which is in progress in each case and to look at it from the view of men of business with large responsibilities. This calls often for the nicest determination and it is for us to form clear and decided opinions which we must be prepared firmly to stand by.

It must be confessed that we are sometimes startled by the confident opinions which are formed upon the facts disclosed in the papers which come before us, cases being placed in a category of excellence which is in no way justified. Such opinions emanate at times from men of good position in the profession and not only from inexperienced examiners. They are largely due, as I believe, to the habit of filling up papers assiduously without due regard to the facts set down and to the dangerous habit thus entailed of disregarding the manner and aspect of the individual under examination. When the questions were fewer and less searching it was formerly the practice to pay closer attention to the examinee and thus to see into the real inwardness of the individual. We must not be slaves to the papers only. And here I would remark that some of these are over-elaborated and almost absurd, especially in the case of the American offices Those of the best British offices are, I consider, all that they need to be and any requirements beyond those laid down in them will tend to error rather than to exactitude for the reasons I have just mentioned.

Some of the most profitable discussions that we have had related to the subjects of albuminuria and glycosuria and we have learned better how to gauge such symptoms. The former subject, I may mention, received masterly treatment from the late Professor Stokvis of Amsterdam in a communication to the Congress of Life Assurance Medical Officers held at the Hague in 1901 and it left little or nothing to be added to the problem. Each of the conditions just mentioned calls for the greatest skill and experience in dealing wisely with them and we are now better than ever qualified to frame prognoses respecting them. We have discussed many other conditions causing anxiety to us in our duties. Amongst these are tuberculosis and the malign influence of alcoholic intemperance. As you are aware, the latter subject comes before us to-night [illegible] one who is well equipped to speak [illegible] we welcome the presence of a [illegible] advocate of temperance in the [illegible]irman of the United Kingdom Temperance and General Provident Institution, who does us the honour to unfold his views before us. For myself, I maintain the views impressed upon me as a clinical physician in respect of the employment of alcoholic liquids for both the healthy and the sick, and I am anything but a *persona grata* to those who inculcate total abstention for everybody. The opinions which I hold and teach are derived from full experience, without any bias in the matter, and with an equally full aversion from the degrading and devilish vice of intemperance in any degree whatever. As hospital physicians for the most part we know too well the ravages wrought by misuse of alcohol in all forms, but we also know well the beneficial uses of it which as honest and level-headed men we are bound to recognise and avail ourselves of in practice. No statistics should shake our convictions or efface our carefully gathered experience in regard to this matter. They will most certainly not shake mine.

We take note of a recently adopted practice in respect of life assurance business whereby lives are now accepted, as is alleged, without any medical examination. It may be surmised that in pursuit of this method more than ordinary care is exercised in considering the fitness of such lives for acceptance and that in conducting this class of business directors take good care to be fortified as far as possible by the opinions of their medical officers in each case. This practice appears to me to be both precarious and troublesome and is certainly designed to attract persons who have no just claim for exemption from the ordinary and proper examination. It probably has its origin in the same causes which so gravely affect the conduct of all business transactions in these days, to wit—hurry, pressure, and furious competition. I venture to believe that this association cannot but discountenance this scheme as little, if at all, justifiable on any merits which it may appear to possess. It does not materially concern any of us and indeed is no business of ours. But we are entitled to our own opinions on the matter. Where we are concerned our duties are made plain for us. We have always to be careful, shrewd, and tactful. We have to be precise and accurate, to do our best for each case, never to be hurried in our work, and to maintain our complete independence. May such principles guide all of us in our daily life assurance work and may our proceedings and efforts here win further triumphs for this important branch of our professional duties.

Some Remarks

UPON

THE MIDWIVES ACT IN ITS BEARING UPON THE WORK OF GENERAL PRACTITIONERS.[1]

BY PERCY ROSE, L.R.C.P. LOND.

THE Midwives Act, 1902, which depends for its successful working on the occasional coöperation of the medical profession, nowhere states who is responsible for the payment of services rendered in connexion with that Act nor what pecuniary value is to be attached to those services. Formerly, while some medical practitioners have flatly refused to attend a midwife's case on any condition, others would give assistance, charging a full fee, or a modified fee, and very often receiving neither. The parish medical officer by reason of the necessary preliminary formalities was but seldom called in. The position of medical practitioners to midwives is distinctly altered by this Act. The midwife now is a different woman. Formerly the practice of the large majority of midwives was guided solely by tradition and cleanliness was optional. Now the Act insures that midwives shall have had some training and experience and any want of cleanliness on the part of the midwife may lead to her suspension by the local supervising authority (Rule F. Central Midwives Board and Midwives Act, Sec. 8, 3) and possibly the removal of her name from the midwives roll (Sec. 3, v.). The reputation of medical practitioners, therefore, who come to the assistance of midwives is now not so likely to be involved in the discredit of a case which has gone to the bad by previous incompetence and dirt.

Having rendered assistance the medical practitioner can only ask for payment from the patient, the midwife, or the public through one of its representative bodies. To look to the patient will in the majority of cases be hopeless. The fees earned, for reasons to be stated later, are above the average medical fees; the patients will certainly belong to the poorer classes, for though this Act was conceived in a West-end drawing-room the women of the West end will be the very last to employ midwives. It is certain that the patient will not be in a position to pay. It would be both absurd and disagreeable to have to look to the midwife for payment and her name is only introduced because some patients consider her responsible for the medical man's fees. The logical but ungrateful husband has already said to the medical man asking for payment: "I shall not pay you. I did not send for you. The midwife sent for you and she must pay you. Besides, if she could not manage the job herself she should not have taken it on." It must be remembered that the parliamentary representatives of the public pushed forward and carried this Act in opposition to the opinion of the majority of the medical profession and that, therefore, the medical profession could disclaim all responsibility for the working of the Act. What now happens is that when certain very well defined abnormalities occur in a midwife's case the midwife by law has to fill up a printed form in duplicate to the effect that the patient "requires medical assistance *at once* on account of," &c. The time of sending the message is recorded in the form and signed by the certified midwife. The medical man receives the requisition, "at once" stares him in the face, and he starts off probably knowing nothing of the patient's pecuniary position and leaving his payment absolutely to pure chance. On his entering the room the midwife pulls out her watch and probably notes the time of the medical man's arrival. A copy of the requisition with the name of the medical man called upon is also forwarded to the local supervising authority and supposing the medical man doubtful of payment does not attend it would not be pleasant for any medical practitioner to have his name publicly served up to his town or county council as refusing medical assistance. The public must see to it that it does not occur.

To insure the successful working of this Act the coöperation of the medical profession and of the public is necessary. If the public wish the medical profession to do the work they must see that the profession are paid. The public guarantee that these midwives are reliable, they guarantee also that if medical help is required the midwife will send for assistance; they must also guarantee the payment for that assistance. This must be done through one of its representative bodies. The Poor-law authorities rightly have many rules and restrictions before they allow expense to be incurred on this behalf. The relieving officer has first to be found, and he may take some finding, before a medical order can be obtained. A Poor-law medical officer without a medical order attends at his own risk and afterwards may have to fight for his money, particularly as these midwives' cases may not be paupers or even poverty stricken. The Central Midwives Board or any central Government department is too far removed from the scene of the active work done to make suitable or efficient "checkers" or paymasters. It is the local supervising authority that everything points to as the most suitable body. The local supervising authority is in most cases the county or town council. These councils are already in touch with all the medical men of their respective districts. They now receive all notifications of infectious diseases, including puerperal cases, and they are in the habit of asking the assistance of all the medical practitioners and issuing circulars from time to time to them on prevailing epidemic diseases; also, they are in close touch with the midwives, inspecting their case books, bags of appliances, &c., and even inspecting their very home. They know the medical men and they know the midwives, and it is to the local supervising authority that the midwives have to send within 12 hours a copy of their requisition for medical help. No other public body is so well placed to deal with these cases. They see the requisition, they know the people, and in the interests of the public they should, if desirable, be able to secure a fuller report from the medical practitioner. In the same public interest they could themselves, or through the local sanitary authority, inquire into the whole case and deal with any collusion, incompetence, or imposition.

It is impossible to estimate with mathematical accuracy the precise pecuniary value of the various services medical practitioners may be called upon to render in connexion with this Act. An average must be taken and the best devised scheme will only be a compromise founded on precedent and common sense. The closest precedents are the fees of 3s. 6d. or 7s. 6*d*. paid by the police for medical aid and the fee of

---

[1] Being the substance of the opening speech at a discussion by the Plaistow and Canning Town Medical Society, Jan. 21st, 1904.

£2 paid by the guardians in difficult labour cases. Our ordinary minimum visiting fee of 2*s.* 6*d.* and confinement fee of one guinea cannot apply here In the first place these midwives' calls are emergencies and "at once" is printed on the requisition form. Therefore a special fee is justified. Secon[illegible] the average case, [illegible] es have only to se[illegible] h a medical practitioner forewarned would not accept at an ordinary fee. In some cases the fees, according to the subjoined scale, might appear to be easily earned, but in others, such as eclampsia and dangerous post-partum hæmorrhage, a fee of £5 might be but a poor payment for the work entailed in endeavouring to save life. A distinction is drawn in this scale between those cases where there is time for the patient to make other arrangements for her attendance or for the care of her child and those cases where immediate treatment is required. In the first class payment for a single opinion and advice is asked for. In the second a larger fee, up to £2, is put down which, of course, includes after-attendance up to the tenth day. Every local supervising authority should be asked to guarantee the payment of some such fees when incurred in giving assistance to the cases of certified midwives in private practice. This, of course, does *not apply to the midwifery practice of hospitals or training* institutions.

Subjoined is the list of conditions, copied from Rule E, 17, Central Midwives Board, as examples of circumstances in which the "midwife must decline to attend alone, and must advise that a registered medical practitioner be sent for." For the purposes of this article a suggested scale of minimum fees has been placed alongside.

SUGGESTED SCALE OF MINIMUM FEES.

(*a*) In the case of a pregnant woman:—	
(1) Where she (the midwife) suspects a deformed pelvis, (2) where there is loss of blood; and (3) where the pregnancy [illegible] condition	[illegible] and advice: [illegible] all, 3*s* 6*d.*; [illegible] ht call, [illegible] *s.* 6*d.*
(*b*) In the case of a woman in labour:—	
(1) In all presentations other than the uncomplicated vertex or breech	£2
In all *cases of breech presentation* in primiparæ	£1 10*s.*
In all cases of flooding and convulsions	£2
Also whenever there appears to be insufficient room for the child to pass or when a tumour is felt in any part of the mother's passages	£2
(2) If the midwife when the cervix has become dilated is unable to make out the presentation	Opinion and advice day call, 3*s.* 6*d.*; night call, 7*s.* 6*d.*
(3) If there is loss of blood in excess of what is natural, at whatever time of the labour it may occur	*Up to £2.*
(4) If an hour after the birth of the child the placenta has not been expelled and cannot be expressed (that is, pressed out), even if no bleeding has occurred	Manual removal, 10*s.* 6*d.*, in addition to the day or night fee of 3*s.* 6*d.* or 7*s.* 6*d.* Instrumental, £2.
(5) In cases of rupture of the perineum or other serious injuries of the soft parts ...	Operation £1 1*s* in addition to the day or night fee of 3*s.* 6*d.* or 7*s.* 6*d.*
(*c*) In the case of lying in women and in the [illegible] Whenever [illegible] he woman [illegible] but in all [illegible] the sub- [illegible]	
I. The mother:—	
(1) Abdominal swelling and signs of insufficient contraction of the uterus... ...	Day, 3*s.* 6*d.*; night, 7*s* 6*d.*
(2) Foul-smelling discharges	£2.
(3) Secondary post partum hæmorrhage ...	£1 1*s.*
(4) Rigor	£2.
(5) Rise of temperature above 100·4° F. with quickening of the pulse for more than 24 hours	£2.
(6) Unusual swelling of the breasts with local tenderness or pain	Day, 3*s.* 6*d.*; night, 7*s.* 6*d* Operation and dressings, £1 1*s.* in addition.
II.—The child:—	
(1) I[illegible] eyes, eyelids, and [illegible]; (5) syphilitic appearance of the skin in certain parts; (6) illness or feebleness arising from prematurity; (7) malignant jaundice (icterus neonatorum); (8) inflammation about the umbilicus (septic infection of the cord)	Opinion and advice day, 3*s.* 6*d*; night, 7*s.* 6*d.*
(*d*) In all cases of the death of a woman during pregnancy, labour, or lying-in	Inspection: day, 3*s* 6*d.*; night, 7*s.* 6*d.*

Anæsthetist (if required), not being the assistant or employer of [illegible] paid according to the time [illegible] 10*s.* 6*d.*; over 30 minutes, £1.

In country districts mileage to the nearest available medical man to be taken into account.

Barking-road, E.

THE SURGICAL TREATMENT OF PERIGASTRIC ADHESIONS.

BY E. PERCY PATON, M.D., M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO WESTMINSTER HOSPITAL.

THE surgical treatment of diseases of the stomach has come very prominently before the profession during the last few years and it has been found possible to give relief to many patients who had previously been the subjects of dyspepsia incurable by other means. Among the various causes amenable to operative treatment may be mentioned adhesions between the stomach and some other neighbouring organ. Although this cause is not forgotten by those who have written on gastric surgery it does not seem always to have received that attention which its importance in some cases deserves, for as operative experience accumulates it becomes more and more evident that in certain cases adhesions, and they alone, may be the cause of abdominal pain and digestive disturbances of a more or less severe kind, when all other disease of the stomach has been for a long time a thing of the past. Some idea of the frequency with which adhesions about the stomach may be expected to be present may be obtained from the following figures. It has been shown by post mortem records that in about 5 per cent.[1] of examinations evidence of an active ulcer of the stomach or a scar of an old one is present; it is also stated by Fenwick[2] that in 40 per cent. of such ulcers there are adhesions, so that these figures seem to show that in about 2 per cent.[3] of persons adhesions will be found to be present if the gastric region be carefully examined after death. Of course, here, as in other regions of the abdomen, for example about the appendix, it is only a small residuum of cases in which any symptoms arise in connexion with these adhesions. The following causes may be assigned for these perigastric adhesions in addition to ulceration of the stomach and duodenum. gall-stones in the gall-bladder or in the common or cystic bile duct, traumatism, malignant disease, pancreatic disease, umbilical hernia,[4] and possibly tubercle and syphilis. Of these various causes, however, only those [illegible] or duodenal ulceration or of [illegible] e at all common and, speak[illegible] h from a practical point of [illegible] e situation of these adhesions is of some importance and it has been found by Fenwick[5] that in 123 cases the adhesions were to the pancreas, the liver, or to both these organs in 92 cases; in the remaining 31 cases the stomach was attached to the colon, the liver and colon, the spleen, the mesentery, or to three or more organs at once. Adhesions to the anterior wall seem to have been absent in all the abdomens he examined. The situation of the adhesion is important in view of what appears to be the fact that when symptoms are due to adhesions only it is usually in cases where the attachment is to one of the more mobile organs, and so is more likely to be dragged upon, that these arise. The nature of the connexion with other parts may be roughly classified into two varieties: (1) those in which the attachment is close and the connexion broad and covering a wide area, in which case the organs to which it is usually fixed are either the liver or the pancreas; or (2) the adhesion may be long and slender, or cord or wire-like, this variety being more usual to the colon, gastrohepatic omentum, gall-bladder, or to the anterior abdominal wall; this last point of attachment, however, is not at all common.

---

[1] Bird. [illegible] Dec. 20th, 1900.

A very unusual variety of fixation is that which occasionally occurs to the anterior abdominal wall, forming with the infiltrated stomach wall and the thickened abdominal parietes a marked abdominal tumour which may easily be mistaken for a new growth. The condition has been described as one of plastic perigastritis, and such cases have been put on record by Billroth,[6] Mikulicz,[7] Fenwick,[8] Terrier,[9] Hofmeister,[10] and Mayo Robson,[11] and they have even been treated with success. The production of these extensive adhesions may not improbably be caused by a local perforation of the stomach, the extravasation having been limited by adhesions; the result has been the setting up of a chronic inflammation producing infiltration of the abdominal wall as well as the surrounding parts and so causing the mass which could be felt. In several cases the mass has been thought to be malignant disease until operated upon and the microscopic finding and the ultimate result of the case have shown this to be an error.

The changes which the stomach may undergo as the result of its attachment to other parts may be very marked or they may be slight. The pylorus may be very narrowed by adhesions which when separated allow it fully to attain its normal lumen. In the one or two cases that I have seen this has usually been the result of antecedent trouble in the gall-bladder, though I have seen a similar condition apparently due to a healed gastric ulcer. In other cases described the stomach has been nearly divided into two parts about its middle by an adhesion and has returned to its normal shape on the division of a simple band, as in a specimen described by Fenwick. It is in such cases that the best results may be expected from operation. Other effects produced are dilatation by traction or interference with the motility and power of contraction of the organ, or possibly by the prevention of contraction of an ulcer, which may by this means be hindered from healing. As, however, in the last-mentioned condition of parts the adhesion will be in the great majority of cases on the posterior aspect of the viscus, and to such an organ as the pancreas, there will be little likelihood of surgery being of any use here by division of the adhesions, though relief may sometimes be given to the symptoms to which the adhesions give rise by a gastro-jejunostomy, as will be mentioned later.

The history of cases suffering from trouble due to adhesions is usually a long one and many varieties of treatment have been tried only to find that no relief has been obtained. The symptoms which the patient finally complains of have not infrequently been preceded by those which are more characteristic of gastric ulcer or gall stone colic These more acute symptoms have passed off and have left the chronic trouble upon which no treatment seems to have more than a very temporary effect. Of this residual trouble pain is the most common and characteristic symptom. Sometimes this pain is almost constantly present to a greater or less extent; in other patients it is only present at times. One of its most marked features is the way in which this pain is not infrequently almost confined to one location; it is also of very variable severity, being sometimes so bad as to double the patient up, at other times and in other cases only amounting to very considerable discomfort. It is not infrequently not at all influenced by taking food, indeed in some patients eating seems to relieve the trouble, possibly by filling the stomach, so that the fixing band is no longer dragged upon. It is not uncommonly greatly influenced by the position of the patient, lying down sometimes giving very great relief; perhaps in such cases the adhesions which fix the stomach are only pulled upon in the erect posture. Exertion of a more or less violent character seems in some persons very liable to bring on the pain, sometimes quite suddenly and in great severity. Occasionally the pain is much relieved by firm pressure over its seat or by tightly bandaging the abdomen, in which case it bears some resemblance to that caused by enteroptosis. Local tenderness to a greater or less extent is a very frequent, indeed it appears to be an almost constant, feature of the trouble; this tenderness is sometimes confined to quite a limited area, which area may be the chief seat of the pain, though this is not always so. The points above referred to with regard to the pain are well described in two papers, one by Caldwell[12] and the other by Bird,[13] to which reference will again be made in connexion with the cases which will be cited. Vomiting does not seem to be very frequently present, though it is occasionally troublesome; it usually seems to occur at irregular intervals and for no very special cause that can be discovered; it may or may not bring relief to the pain. The sickness in typical cases is not usually severe enough to interfere to any great extent with the general health of the patient. In those cases in which the adhesions connect the stomach and gall-bladder jaundice may occur and may be persistent for a long period, as in one case of mine, but as a rule it is only a fugitive condition coming and going in an irregular manner. A very noticeable feature is commonly the very slight influence that careful dieting seems to have on the pain and discomfort; this in itself is suggestive of the true cause of the trouble, as in most digestive disturbances some relief can usually be got by careful feeding, even if the case cannot be cured in this way. It is also noteworthy that in spite of the long continuance of the trouble the general health as a rule does not suffer to the extent that might be expected; there are, however, not infrequently exceptions to this statement. Physical examination will as a rule reveal nothing beyond the tenderness to which reference has already been made; the gastric juice is normal and there are in general no signs of gastric dilatation. At other times, however, evidence can be obtained of an increase in size of the organ and this may be very marked and is due to some interference with the motility of the viscus or to some narrowing of the pylorus or narrowing of the stomach at some other situation. Local areas of dulness have been described as occurring in this trouble, but this must be very uncommon, for as a rule there is nothing present that can give rise to this dulness. In the rare cases in which a tumour is present this may be of considerable size and be so firm to the feel as to lead irresistibly to the belief that the trouble is malignant with possibly some adhesions to the anterior abdominal wall in addition In such circumstances the age of the patient, and more especially the long continuance of the illness without a very serious influence on the general health, will be of very great use as an aid in arriving at a correct opinion as to the nature of the trouble.

A careful consideration of all the features of any particular patient's troubles may lead to the conclusion that these troubles are almost certainly due to adhesions, but in most cases only a tentative diagnosis can be made which will be sufficient to warrant strongly urging an exploratory operation on a patient who has been for, perhaps, a very long time a sufferer from the symptoms detailed above without obtaining any relief from medicine and dietetic treatment. The following cases illustrate this condition; of these, the first four were under my own care or observation, while reference is given to the sources from which the others are taken.

CASE 1.—A woman, aged 30 years, had suffered on and off for several years from pain and discomfort in the upper part of the abdomen, a little to the right of the umbilicus being its main seat; this pain was of a gnawing character and did not seem to have any direct reference to food though care in diet assisted the trouble to some slight extent There were no vomiting and no evidence of dilatation of the stomach; there had never been any jaundice. There was nothing to be felt in the abdomen but there was a little tenderness a little below and to the left of the region of the gall-bladder. There was no wasting and the general health, except in so far as it was interfered with by the pain, was fair. The patient was, however, obviously rather neurotic. An incision was made over the seat of the pain and nothing abnormal was found save a few thin adhesions between the pylorus and the liver and the gall-bladder which were separated; the organs themselves seemed in every way normal. The interference greatly relieved the patient's troubles.

CASE 2.—A man, aged 48 years, had for years suffered from dyspepsia which had rendered him unable to do his work as a clerk on account of the attacks of vomiting and pain to which he was subject; the pain in this case was certainly aggravated by want of care in diet and relieved, though not cured, by careful feeding. On examination there was nothing abnormal to be felt in the abdomen but the stomach was found by percussion to be somewhat dilated. He was carefully treated by dieting and washing out the stomach for some time and was by this means considerably improved and went out of the hospital only to return shortly as bad as ever. During treatment he put on weight but as soon as this was stopped he again began to lose weight. He was readmitted and the abdomen was opened in the middle line; the stomach was found to be somewhat, but not very markedly, dilated, the pylorus was firmly adherent to the under aspect of the liver, and these adhesions caused a considerable narrowing of its lumen. The cause of the adhesions was an old ulcer of which a scar could be felt, but the narrowing seemed clearly to be due to the adhesions and not to the scar. As it seemed certain that if the adhesions were separated they would be sure to re-form a pyloroplasty was performed; this entirely relieved the patient's symptoms for the time, though five months later he began to have some recurrence of a milder sort than had previously been the case. Possibly it would have been better to perform a gastro-jejunostomy for this man in the first instance, but if his troubles should recur further it is proposed to do this then.[14]

CASE 3.—A woman, aged 51 years, had been subject for some years to attacks of violent pain in the epigastrium which lasted for a few hours and then disappeared; they were usually accompanied by vomiting. For the last year she had been jaundiced more or less and she had been losing a little flesh, but not to a marked extent. On examination she was markedly jaundiced. There was nothing to be found abnormal except in the abdomen which was distinctly tender in the epigastrium under the right rib margin; here, too, was to be found a patch of dulness extending down towards the umbilicus; the fæces were clay-coloured. The case was thought to be one of gall-stones and an incision was
was at once
to the stoma
deal of diffic
could be explored thoroughly but they were found to be clear of stones; the gall-bladder was not distended; the abdomen was therefore closed, only adhesions having been separated. The patient, after causing some anxiety for a day or two owing to the fact that she vomited a good deal and that there was a considerable amount of blood in the vomit, did very well; she gradually lost her jaundice and never had any more attacks of pain. I saw her a short time ago, eight years after the operation, and she is still in good health and with no return of her previous troubles.

CASE 4.—This case seems to show how, at any rate in some cases, the pain of malignant disease of the stomach may be due to adhesions. A man, aged about 50 years, was sent to me by Mr. J. R. Johnson of Richmond on account of pain in his abdomen. He had been gradually losing flesh and his medical attendant and I both agreed that it was almost certain that he had malignant disease of the cardiac end of the stomach as the pain was seated in this region and it was doubtful if a mass could not be felt there. The man was told that nothing could be done for him but an operation and that it was in the highest degree improbable that this would do him any real good; but he was very anxious to have anything done that offered him the least prospect of relief from his pain. The abdomen was opened in the middle line and it was at once found, as was expected, that there was a considerable mass of malignant disease extending up under the left rib margin; there were also some adhesions to the anterior abdominal wall; these were separated and the abdomen was closed. The patient ultimately did well in spite of a very sharp attack of pneumonia, the interesting point for the present purpose being that from the time of the operation to the time of his death about two months later he had no return of the severe pain to which before the operation he had been subject. It seems likely that this had been due to the pulling on the adhesions though, of course, it is well known that merely opening the abdomen will sometimes relieve the pain of a patient with abdominal new growth when no adhesions have been separated.[15]

F. D. Bird[16] relates nine cases which were under his care and in which the symptoms were entirely relieved by the separation of adhesions. The following is a brief summary.

CASES 5, 6, and 7.—Three patients had been chronic invalids for years. They had all at one time had clear symptoms of gastric ulcer; this had left them with chronic pain which incapacitated them from working; they were found to have adhesions fixing the posterior aspect of the stomach and were practically cured by the division of these adhesions.

CASES 8 and 9.—In two cases there were jaundice and extensive adhesions around the gall-bladder and the stomach, but no evidence of a stone was present at the time; the division of the adhesions also proved satisfactory.

CASE 10.—Another case had in addition to the pain a distended gall-bladder; wire-like adhesions between it and the stomach were divided with complete relief.

CASES 11, 12, and 13.—In three other cases the adhesions were of a wire-like character between the stomach and lesser omentum and in one of them a previous operation had failed to discover these. Bird believes this to be due to the fact that the bands did not become obvious until the stomach was drawn down in such a way as to make them tense and so it was not at all difficult for them to be overlooked. In these cases, too, the result of division of the bands was all that could be desired.

Hale White[17] recounts five cases of which the following abstract may be made.

CASES 14 to 18.—Three occurred in women and two in men. All had been sufferers for a very long time; two of them were very much reduced by their illness and these two died as the result of the operation. The other three were marvellously relieved by the separation of various adhesions which seem in all these cases to have been due to old gastric trouble. He points out that in a patient who has been long the subject of local pain from a cause such as we are discussing the "pain habit" becomes so established that the best result may not be seen at once, even when the cause has been removed, but that time will sometimes show an improvement later. This was clearly so in one of his cases and something of the same sort was noticed in a case that I have heard about from another source.

CASES 19 to 28.—Mayo Robson[18] gives ten cases, five in men and five in women, most of whom had been sufferers for a considerable number of years from gastric trouble of a more or less severe kind. They were all greatly relieved and in most of the cases quite cured by the separation of adhesions around the stomach, but in one case it was found necessary to perform gastro-jejunostomy as the adhesions were too extensive to be separated. The most prominent symptom in general was pain with sometimes vomiting and occasionally jaundice.

CASE 29.—Rosenheim[19] gives a case in a man, aged 27 years. He had been a sufferer from discomfort and pain after almost every meal for a long time. Exertion also gave him epigastric pain. He had a good appetite and was well nourished; the kind of food which he took did not seem to have any influence on the amount of trouble from which he suffered. There was a little ter
He had been carefully treated
At the operation he was found
of the stomach to the liver
these were separated and a complete cure followed.

In a paper by Lauenstein[20] seven cases are recounted of which brief abstracts are given below.

CASE 30.—A woman, aged 22 years, had suffered for a long period from severe epigastric pain and occasional vomiting; the pain was somewhat relieved by pressure over the stomach, but nothing did it really much good and it was only controlled by morphine. An exploratory operation revealed extensive adhesions between the stomach, the gall-bladder, and the duodenum; these were separated and re-adhesion was prevented by inserting a piece of sterile oil-silk between the parts for 48 hours; no cause was found in the organs for the adhesions but she was completely cured of her pain.

CASE 31.—A female, aged 30 years, had 15 years before swallowed some caustic fluid, since which time she had been subject to frequent attacks of violent pain, some distension over the stomach with great tenderness, a feeling of fulness, and vomiting. The operation showed adhesions between the stomach and the large and small intestines; division of these resulted in a complete cure.

CASE 32.—A woman, aged 66 years, had at the age of 27 years symptoms of ulcer of the stomach. She had since then been apparently well till the last few years, during which time she had been an almost constant sufferer from epigastric pain, for which she had used a good deal of morphine. She vomited occasionally but there was no loss of flesh. Hydrochloric acid was absent from the vomit. An exploration brought to light an adhesion between the transverse colon and the small omentum, which passed over the pylorus in such a way that its lumen was very much narrowed. On division of this adhesion the lumen of this part of the alimentary tract was restored to normal and the patient was quite relieved. Unfortunately, the trouble recurred in a month or two but the patient was again operated on with success, though when the case was reported no very long time had elapsed since the second operation.

CASE 33.—Early in life a woman, aged 45 years, had been a sufferer from gastric trouble. Since then she had been free until a year previously. She then began to have stomach pain which drug treatment tried for several months did nothing to improve. The pain was of a dull aching kind; the general condition remained good. Bands connecting the stomach and the colon, and also passing between the different parts of the colon, were found and divided, resulting in complete relief.

CASE 34.—The next case is that of a woman, aged 28 years, who had suffered for several years from pain in the back and the stomach which was often so severe as to prevent her from getting about; she also had a good deal of epigastric tenderness; there was no jaundice. Treatment by drugs for six months was tried without result. At the operation many connexions between the gall-bladder, the pylorus, and the colon were divided and some gall-stones were removed and ultimately a cure resulted. In this case it is not at all improbable that the stones were the real cause of the pain and not the adhesions, though Lauenstein does not seem to think so.

CASE 35.—A woman, aged 40 years, had been the subject of pain and tenderness located in the left half of the epigastrium for about 13 years; there was some tenderness over the painful spot and she was sometimes sick. All kinds of medical treatment had been tried with no satisfactory result and she had now taken to morphine to relieve her troubles. At the operation there was found a long band passing from the liver to the anterior abdominal wall and running in such a direction as almost to divide the stomach into two parts; this was divided. There were also some broad attachments of the stomach to the posterior abdominal wall and to the under aspect of the liver but these were not interfered with. The result was quite satisfactory.

CASE 36.—Lauenstein also recounts a similar case in a man, aged 52 years, but this patient was in a much reduced condition at the time of the operation and also had some lung trouble and died shortly after the division of extensive adhesions, so there was no opportunity of seeing if any relief would have resulted. This case is referred to to show that in much reduced subjects the operation may not be devoid of risk.

The six cases of which brief notes will now be given are all examples of the presence of a distinctly palpable mass due to what has been termed plastic perigastric inflammation. The importance of these cases lies in the difficulty of diagnosing them from new growth, more particularly in view of the fact that new growth is common, while this class of case is distinctly rare.

CASE 37.—Hofmeister[21] recounts a case in which there had been long-standing abdominal pain and gastric trouble. On examination of the epigastrium a distinct tumour could be felt but it was thought doubtful if this was in the anterior abdominal wall or whether it was a malignant growth. At the operation it was found to be a mass formed by adhesions of the stomach to the liver, the spleen, and the anterior wall. In separating these connexions the stomach was torn and it became necessary to finish the operation as a pyloroplasty. The patient did well and was quite cured of all gastric trouble

CASE 38.—Billroth[22] gives a case in which for many years a patient had suffered from pain in the stomach and other digestive troubles; a mass was felt in the epigastrium which on exploration was found to be formed by a chronic ulcer of the stomach which had attached itself to the anterior abdominal wall, a considerable inflammatory thickening having formed around it. The whole mass with the ulcer was excised by an operation of considerable difficulty; the patient did well and was completely cured of all his previous troubles.

A case is described by Terrier[23] as follows:—

CASE 39.—A woman, aged 62 years, had been losing flesh and suffering from abdominal pain and occasionally passing blood in her motions for a considerable period. On examination a mass was felt in the abdomen just below the rib margin. An exploration revealed adhesions between the stomach, the liver, and the anterior abdominal wall and also some enlarged glands at the greater curvature of the stomach. The adhesions were separated and the abdomen was closed, the case being thought malignant. A year later the patient was quite well and had put on 10 pounds in weight.

CASE 40.—Terrier describes also an almost exactly similar case treated in the same way in which the patient had occasionally some pain after the operation for about six months and then got quite all right. In this case some of the thickening which formed the mass was removed and was found by the microscope to consist of fibrous tissue only.

CASE 41.—Klausner[24] gives the following description of the case of a servant girl, aged 21 years. Her history was that she had had two attacks like those caused by an ulcer of the stomach, the last being three years before she came under observation. Since the last attack she had never been properly free from pain, but sometimes her attacks were worse than at others and she occasionally vomited, but she did not appear to be at all ill-nourished. On examination there was found to be marked tenderness under the left rectus which was kept somewhat rigid; beneath it was an ill-defined mass the nature of which seemed very doubtful. As it was thought that it might be syphilitic she was treated with iodide of potassium without any benefit. An exploration showed the mass to be due to the inflammation from a gastric ulcer extending to the anterior abdominal wall. The ulcer and the adhesions were excised and the opening was closed. The patient did well and six months later was seen in good health, having lost all her previous pains.

CASE 42.—The last case to be referred to is one by Mikulicz[25] as follows. A servant girl, aged 24 years, had been anæmic for many years but her present illness dated from five months before she came under Mikulicz's care; during that time she had suffered from all the symptoms of gastric ulcer—pain after food, vomiting, with occasionally blood in the vomit, and loss of appetite; she had also lost a good deal of flesh. On examination she was found to be very anæmic and badly nourished; through the upper part of the thin abdominal wall under the left rectus was to be felt a rather tender mass of about the size of a goose's egg. The abdomen was opened in the middle line and the general peritoneal cavity was only entered by prolonging the incision down to the umbilicus; it was then found that the stomach, which was large, was here free from the abdominal wall, but was elsewhere widely attached to it. The attachment was divided with scissors. It was now easily demonstrated by invaginating the healthy stomach wall that in the centre of this mass of adhesions was an excavated ulcer. The whole mass was therefore excised and the gap thus made in the stomach wall was closed with sutures. The patient did well and was seen three months later in good health and completely free from any gastric trouble. Mayo Robson[26] has also just recently published some further cases of a very similar character.[27]

[25] Loc. cit.

[26] Mayo Robson: Brit. Med. Jour., 1903, vol. i., p. 951.

[27] Since the above was written I have had a case under my care in which a palpable mass in the region of the pylorus was present in a

The treatment of these cases resolves itself in the first instance to verifying the diagnosis by an exploratory incision, which, as has been already indicated, should in most cases be strongly recommended to patients with the symptoms which have been referred to above and in whom a fair trial of dietetic, drug, and general hygienic treatment has not proved successful. If adhesions are found they should be carefully separated or divided if this is possible; if none is at first detected the stomach should be dragged downwards and in other directions so as to make visible bands which might, as has been noted by Bird,[28] have been otherwise overlooked. The difficulty now presents itself of preventing the adhesions from re-forming and various methods have been suggested. I think that there can be little doubt that the most important is the absolute exclusion of sepsis, but this may perhaps be taken for granted. It is also of the greatest importance that no antiseptic should be used within the abdominal cavity in the course of the operation; if any fluid at all is to be introduced it should be sterile normal saline solution. The interposition of a piece of omentum between the separated surfaces has been advised, but it seems doubtful if this is really of any use except as allowing the formation of a looser sort of adhesion, but if it is possible it is important to cover in any large raw surfaces by drawing together the peritoneum around with a stitch or two in such a way as to cover such surface in with smooth peritoneum. In one of the cases recounted above it will have been noted that the separated surfaces were prevented from coming together by inserting a piece of sterile oil-silk between them, but it seems usually better not to insert any foreign body in this way, as such substances in most cases seem rather to act as an irritant and to promote rather than to prevent adhesion.

A series of most careful and interesting experiments have *been made by Karl Vogel*[29] *on the formation and prevention* of intraperitoneal adhesions in which in addition to the means already mentioned the following conclusions were come to after the trial of a large number of different substances to separate raw surfaces of peritoneum which were [illegible] them was of very much [illegible] t results were obtained [illegible] introduced in some quantity into the abdomen or the use of a small quantity of sterile solution, of one part of gum arabic in two parts of saline solution. He found, however, that of much more importance in the prevention of re-adhesion was the promotion of movement among the viscera by allowing the patient to move from side to side in bed more than is usual after abdominal section, by employing gentle massage to the abdomen, and particularly by promoting peristalsis, so that the parts liable to adhere are not likely to lie at rest in contact with one another for long together. For this purpose he found that mild laxatives and the use of atropine, physostigmine, and also salicylates seemed of considerable assistance. *Some of these means seem* hardly suitable to some of the cases with which one has to deal but the principle which they try to carry out is clearly a good one and the old treatment of keeping cases of abdominal section too rigidly at rest with the bowels confined has almost given way now to the much better plan of opening the bowels at a very early date except when there is some indication very definitely against this measure.

In a certain number of cases it may be found that the separation of adhesions may be clearly not feasible, or they may be so extensive that it may seem practically certain that even if they were divided re-formation would be practically certain. In this case there are two other means that may be resorted to, especially in those cases where the trouble seems to be due to narrowing of the pylorus or interference in any other way with the stomach emptying itself; these means are pyloroplasty and gastro-jejunostomy. Of the two the latter is usually the better operation, as its results seem to be the more certain, but in some cases, especially when the adhesions are very extensive, the former may be more adviseable. The way in which these two procedures act is by allowing the stomach to empty itself more easily and so preventing distension or the traction on the adhesions which may occur when the stomach is over or even moderately full. When adhesions on the posterior aspect are the reason, or partly the reason, which prevents an ulcer from cicatrising, the rapid emptying of the stomach which the latter of these two operations allows, by permitting contraction and at the same time rapidly getting rid of the food which by its residence in the stomach may irritate the ulcer, will often be of material assistance in getting a chronic ulcer to heal.

As to the results of the operation little need be added to what is said above in recounting the cases, but it would be a mistake to think that every case is likely to be as successful as those referred to here, as it is not impossible that cases are operated on and when not successful nothing more is heard of them, but even should this be the case the results here shown are sufficient to indicate the really brilliant successes that in suitable cases may be obtained. Patients whose lives have been for years a misery and who have been rendered unfit for any sort of employment and have therefore been made chronic invalids may in some cases be restored to complete health again.

Park street, Grosvenor-square, W.

---

man, aged 50 years. There were some gastric pain, dilatation of the stomach, and loss of flesh. Operation showed the mass to be adhesions about the pylorus, which were separated with satisfactory result.

ON CONGENITAL OCCLUSION OF THE ŒSOPHAGUS.[1]

BY WILLIAM THOMAS, F.R.C.S. ENG.,
CONSULTING SURGEON TO THE BIRMINGHAM CHILDREN'S HOSPITAL;
SENIOR SURGEON TO THE ROYAL ORTHOPÆDIC AND
SPINAL HOSPITAL, BIRMINGHAM.

CONGENITAL occlusion of the œsophagus has not had much attention given to it in text-books devoted to diseases of children nor is there much said about it in works on pathology and morbid anatomy, in which it is usually dismissed in a few lines under the head of congenital abnormalities. This probably arises from its rarity or perhaps from the practitioner failing to recognise it, not suspecting such a condition. I hope this short communication may be the means of directing attention to it and also of suggesting some successful method of treatment as in all the cases hitherto recorded the patients appear to have died.

In October, 1901, my attention was called to an infant, two days old, who was constantly sick and who was said to have vomited all that had been given it since birth. The nurse also told me that the sickness was of an unusual character and seemed rather to be due to inability to swallow properly than to any gastric trouble. The child looked strong and healthy. When the finger, the nipple, or the teat of a bottle was introduced into the mouth the child seized it and sucked strongly and eagerly and would take a few teaspoonfuls of liquid until it seemed to excite coughing and signs of suffocation with return of apparently all that had been taken. I thought that a little of the food was retained and therefore ordered the child to be fed at intervals with very small quantities at a time. On the next day the patient was no better. The vomiting and choking continued much as before. I attempted to pass a bougie but the point returned into the mouth. I then explored the pharynx with my finger and found that the lower part was considerably dilated and still contained about a tablespoonful of the fluid that had been given. There appeared to be no continuation beyond a point about the junction of the pharynx and the œsophagus, the finger easily reaching to the extremity of a cul-de-sac about that situation. It was pitiable to see the child struggling for life and food and the eagerness with which an attempt was made to swallow, but there was nothing to be done and on the fourth day death ensued. I could not obtain a post-mortem examination and therefore I am unable to say what was the condition of the œsophagus beyond the cul-de-sac or whether the rest of the alimentary canal was normal or otherwise. I had never even seen such a case before and could not find much information in any text-book of surgery or of diseases of children. (The most complete account is Holmes's) I concluded that it was one of those very unusual abnormalities which one only sees once in a lifetime.

Some months ago, whilst looking over the stock of a second-hand bookseller, I came across a copy of Gibson's

---

[1] A paper read before the Birmingham Branch of the British Medical Association, November, 1903.

"Anatomy." Evidently this work had been a favourite text-book, as it had passed through several editions in a few years—the third in 1688, the fifth in 1697, and the sixth in 1703. This last is in the library of the Birmingham Medical Institute. In the fifth edition and later there is a case described so similar to the one which I have mentioned that I hope I may not be considered tedious if I give it in full. Dr. Gibson had the opportunity of making a post-mortem examination, which he rather quaintly describes. His account is as follows:—

> About November, 1696, I was sent for to an infant that could not swallow. The child seemed very desirous of food and took what was offered it with greediness, but when it went to swallow it, it was like to be choaked, and what should have gone down returned by the mouth and nose, and it fell into a struggling convulsive sort of fit upon it. It was [illegible] was two days old when I was called to it, but [illegible]
>
> The par [illegible] e it opened I took two physicians and a surgeon with me.
>
> On opening the abdomen first, the guts had some of the meconium remaining in them, though the child had gone two or three times to stool. The stomach had in it a pretty deal of a slimy sort of liquor (or gelly rather), somewhat like thick (strained) water-gruel. [I shall not mention any observations upon other parts of the abdomen, as being not to our present purpose.]
>
> Then we cut open the thorax and taking out the gullet with the wind-pipe, lungs, &c., continued to the stomach. Then we made a slit in the stomach and put a pipe in its upper orifice, and blowing, we found the wind had a vent, but not by the top of the gullet. Then we carefully slit up the back side of the gullet from the stomach upwards, and when we had gone a little above half way towards the pharynx we found it hollow no further. Then we began to slit it open from the pharynx downwards, and it was hollow till within an inch of the other slit, and in the imperforate part it was narrower than in the hollowed. This isthmus (as it were) did not seem ever to have been hollow, for in the bottom of the upper and the top of the lower cavity there was not the least print of any such thing, but the parts were here as smooth as the bottom of an acorn cup.
>
> Then searching which way the wind had passed when we blew from the stomach upwards, we found an oval hole (half an inch long), on the fore side of the gullet opening into the Aspera Arteria, a little above its first division, just under the lower part of the isthmus above mentioned.

The remainder of the history of this case does not much affect the question of treatment, so I omit it.

A further search in the library of the Birmingham Medical Institute disclosed a series of cases. They are contained in a paper presented as a thesis for the degree of Doctor of Medicine by H. Hirschsprung, Copenhagen, a *résumé* of which was published in the *Medico-Chirurgical Review* in 1862. 14 cases are mentioned, in 11 of which there is a complete report of the post-mortem appearances. In all the cases the upper part of the œsophagus was found expanded into a large sac formed of its normal membranes and terminated in a rounded shape at different distances from the mouth. In cases in which the upper end of the œsophagus was patent for the greatest extent the occlusion was half an inch from the bifurcation of the trachea.

There would appear to be two forms of congenital occlusion, one in which the upper and lower portions are united by a fibrous cord, and another in which the lower part opens into the trachea or into one of the bronchi. This latter seems to be the condition in by far the greater number—in fact, it would appear to me to be the usual state. It also happened in several cases that other abnormalities were present, as atresia ani, rectal deficiency, abnormal termination of the rectum, or imperfect development of the pelvis.

It is not my intention to discuss the causes of the malformation. I have formed no settled conviction whether it is due to arrested development or to a pathological process in the fœtus. On the whole I think the balance of evidence is in favour of arrest of development.

Before proceeding to consider the treatment of this condition I should like to mention the conclusions which I have come to after a study of the various cases that I have found recorded. These are about 19 in number—namely, Dr. Gibson's, my own, 14 described by Dr. Hirschsprung, three mentioned in the Transactions of the Pathological Society, and one operated on by Mr. F. J. Steward at the Hospital for Sick Children, Great Ormond-street, London, last year. It is probable that the condition is more frequent than has been thought, the comparative rarity causing it to be overlooked or the symptoms attributed to some other cause; but as Dr. Hirschsprung remarks, "If in an institution like the Copenhagen Lying-in Hospital, where 1100 or 1200 parturient women are annually taken in, seven cases of a congenital malformation may be met with in the space of 16 years we are forced to deny its excessive rarity." The most frequent pathological condition is that in which the lower part of the œsophagus opens into the trachea; the absorption of a small amount of food through this communication may possibly reach the stomach. In one case in which rectal feeding was adopted the child lived 11 days, but otherwise four days seems to be at most the longest period and it is inconceivable that an infant's life could be long maintained on nutrient enemata.

Can anything be done in such cases? Nothing but some surgical operation which will enable the child to be fed. Holmes even thinks there is no objection if the parents wish it, after the inevitably fatal nature of the case has been explained to them. And he suggests a method of operating by which he thinks permanent success might possibly be obtained. First, we must be certain of the diagnosis. This is not difficult. The peculiar character of the vomiting and its persistence should naturally lead to an examination of the œsophagus. The abortive attempt to pass a bougie and the examination with the finger would, unless the upper pervious portion of the œsophagus were unusually long, at once settle the matter. In my case the bottom of the sac was truly, as Dr. Gibson remarks, as smooth as the inside of an acorn cup and no depression of any sort could be felt which might suggest an exit or communication. There is not much time for deliberation. The condition is hardly likely to be noticed until the second day after birth and few of the infants have survived more than four days. It is a question whether the child should be allowed to die or should have the slight chance afforded by operative treatment. Gastrostomy seems to afford the most advantages. Its performance would not be difficult, in fact the simplest that could be done. The opening should be comparatively large and at once firmly united to the skin so that feeding might be commenced immediately. The selection of food and its administration should be carefully attended to and this ought to be watched by the surgeon on every occasion. I do not think the operation suggested by Holmes would be feasible—i.e., to try to bring the two blind extremities into contact. It would be particularly difficult in a baby two days old. There is so little room.

There is one route by which the stomach might be reached and which might be available in a few cases. In the majority the lower part of the œsophagus opens into the trachea just below the larynx. Might it not be possible to open the trachea and in the event of a high opening of the œsophagus to pass food into the stomach by this route, and for a while, to gain time, an indiarubber tracheotomy tube in the trachea would prevent food passing down it, and nourishment might be passed into the œsophagus above it? I simply throw this out as a hint for discussion.

I only know of one case which has been operated on—i.e., Mr. Steward's, to whom I am indebted for particulars. The child did not recover but lived for 14 days, the longest time on record. Perhaps in the future, when these conditions are discovered early, greater success may be attained. Rectal feeding has prolonged life in at least one case and might with advantage accompany other treatment, and careful examination should be made to insure that there is no congenital deficiency of the rectum or other part of the alimentary canal.

Birmingham.

A CHART OF STATIC MODALITIES.

By F. HOWARD HUMPHRIS, M.D. Brux., F.R.C.P. Edin.,
HONORARY PHYSICIAN, QUEEN'S HOSPITAL, HONOLULU

I have been induced to draw up the accompanying chart, not because there is anything particularly new in it, but because I can find no similar information put in a concise way in any published work on static electricity. In some text-books there is a list, more or less complete, of the various static currents, and it may be the indication for some of them, but the technique of each—i.e., the arrangements of the electrodes, the spark gap, and the presence or absence of Leyden jars—is either not there at all or only to be found after a tedious and often unsatisfactory search. Another reason why I venture to bring this forward is that with the present partiality for coil work there seems to be a possibility that the very useful static machine may be neglected, and while it is not my present intention to weigh the relative merits of coil and static work I should like to mention that in New York and several large cities of the United States, where physicians have both coil and static machines in use, it is the latter

A CHART OF STATIC MODALITIES.

Class	Name.	Connexions for poles and electrodes.	Leyden jars.	Insulation of patient.	Requisite electrodes.	Spark gap.	Physiology and therapeutics (after Snow).	Special indications.	Remarks.
Conductive.	Static induced.	Both to Leyden jars and both to patient.	Yes.	No.	Metal to bare skin or to mucous membrane.	Closed to begin with and gradually widened until the tolerance of the patient is exhausted.	Subjective: (1) Induces muscular contraction; (2) physiological tetanus; and (3) local vibratory effect. Clinical: (1) Relieves local pain; (2) relieves local congestion and (3) increases secretion.	Obstinate constipation and painful neuroses.	The constitutional effects of this current are practically *nil*.
	The wave current.	Positive to the patient and negative to the ground.	No.	Yes.	Block tin or metallic cloth to bare skin.	As static induced.	Subjective: (1) Local vibratory effect; (2) induces muscular contraction; and (3) physiological tetanus. Clinical: (1) Diminishes local swelling and congestion; (2) local pain relieved; (3) acute muscular spasm relieved; and (4) increase of local metabolism.	Insomnia, facial neuralgia, gout, sprains, asthma, rheumatism, pelvic congestion, lumbago, dysmenorrhœa, impotency, prostatitis, dyspepsia (nervous), gleet, constipation, and goitre.	During the application of this current to extra sensitive areas—e.g., forehead, eye, ear, nose, and throat—it is advisable to do away with the negative grounding. The two forms of the intensification of this current have been omitted; they are more local and less constitutional in their effect. When this (the unmodified) cannot be used, then the static induced current is indicated.
Disruptive.	Sparks, indirect, and friction.	Positive to patient or to platform, negative to ground, and electrode to ground.	Optional but as a rule too severe.	Yes.	Brass balls.	Wide open.	Subjective: (1) Stinging sensation; (2) muscular contraction; (3) blanching, followed by redness, wheals, and even blisters by successive applications; and (4) increase of local secretion. Clinical: (1) Relaxation of muscular spasm; (2) relief of pain; and (3) hyperæmia and swelling lessened.	Muscular, subacute, and chronic rheumatism, locomotor ataxia, rheumatoid arthritis, all deep-seated nervous structural lesions and deep-seated pain, sciatica. Of all local currents the spark is the best diaphoretic.	There is also the direct spark; it is very severe and only of use in humid weather. In other respects it resembles the ordinary spark, but the positive connexion is to the patient and the negative to the electrode. The currents in order of preference for the relief of pain are (1) wave, (2) brush, (3) high-frequency, (4) sparks, (5) breeze, (6) spray, (7) static bath, and (8) static induced.
Disrupto-convective.	Brush discharge.	Positive to ground, negative to patient or to platform, and electrode to ground.	No.	Yes.	Made of wood of various sizes and shapes	Wide open.	Subjective: (1) Increases local secretion; (2) rubefacient, if pushed; and (3) local antisepsis. Clinical: (1) relieves local congestion; (2) lessens local swelling; (3) diminishes local pain; (4) promotes local metabolism; and (5) destroys superficial septic processes.	Early acute rheumatism, sprains, abscess, swelling in fractures, early stages in any acute inflammation, lumbago, gout, otitis media, lupus, tubercle, and any congestion or stasis, with or without germ life.	—
Convective.	Breeze and spray.	Positive to patient or platform, negative to ground, and electrode to ground.	No.	Yes.	Usually brass, point, single or multiple crown, or broom.	Wide apart.	The same as the brush discharge but more irritating and less effective.	—	The positive breeze is stimulating; the negative is sedative. The negative breeze is where the negative pole and the electrode are both grounded and the positive pole is connected with the patient.
	High-frequency.	Positive to ground and *negative to electrode.*	No.	No	Special glass *vacuum.*	Begin with half *an inch and* gradually regulate to capacity of patient.	—	Increases voice range. Piles, *rectal ulcer, fissure, tonsillitis,* catarrh, hay fever, lupus, tubercle, and acne and other skin affections.	Ozone evolved. Vacuum *electrodes without wire are preferable* because they are less liable to puncture, cheaper, and equally efficient.
	High-frequency, specially interrupted.	Both to series interrupter and negative current to electrode, positive current to ground.	Yes.	No.	As ordinary high-frequency.	Wide open.	—	The same as for the ordinary high-frequency current.	Even more ozone is evolved. Note that the positive current comes from that Leyden jar attached to the negative prime conductor and *vice versâ.*
	Potential alternation.	Positive to patient and negative to ground.	No.	Yes.	Water, block tin, wooden, or brass, depending upon work required.	Wide apart (see remarks).	—	Painless, simple, and fairly effective. The indications are the same as for the spark.	Note that the interruption is effected with the stand ball electrode and the prime conductor to which the patient is connected.
	The static bath or general electrification.	Usually positive to patient or platform and negative to ground. *Note.*—These are the usual connexions. It sometimes happens that the reverse may suit certain cases. This does not apply to the high-frequency currents, where the connexions cannot be changed.	No.	Yes.	None.	Wide open.	*All static modalities.*—Circulatory system: (1) Lessen arterial tension; (2) lessen heart frequency; (3) lengthen diastole; and (4) increase pulse volume. Respiratory system: (1) rapid and laboured breathing relieved; and (2) deepened breathing, with increase in elimination of CO_2. Nervous system: (1) relieve irritability; and (2) induce soporific effect. Vaso-motor system: (1) induce diaphoresis; and (2) induce diuresis, with increased elimination of urea. Increase of general metabolism.	Where a general sedative is indicated; congestive headache; as a prelude to, or in conjunction with, other static modalities.	—

upon which they chiefly rely not only for many classes of x-ray work but also for the therapeutical effects of the high-frequency and other currents.

For the column headed "Physiology and therapeutics" I am indebted to Dr. Benham Snow of New York; it is an abstract of one of his lectures and it is with his kind permission that it appears here. The column headed "Special indications" is by no means complete, for while many diseases are benefited by the several currents and many more by general electrification to put such down arbitrarily in a chart as a definite indication might be misleading.

In conclusion, I would say that this chart is not intended to replace text-books and practical instruction but rather to codify and to simplify the knowledge thus acquired and afterwards to be used as a means to refresh the memory.

Honolulu.

AGGLUTINATION AND SEDIMENTATION IN HUMAN GLANDERS.

BY C. MONTAGUE HEANLEY, M.R.C.S. ENG., L.R.C.P. LOND., D.P.H.,

SECOND ASSISTANT AT THE CLINICAL AND BACTERIOLOGICAL DEPARTMENT OF THE MIDDLESEX HOSPITAL.

As long ago as December, 1896, Dr. J. McFadyean of the Royal Veterinary College made the observation that the serum of glandered horses caused marked agglutination of the bacillus, while that of two normal horses had no such effect.[1] Later Mr. A. G. R Foulerton, using bacilli isolated from the case, observed that the serum of a stable boy suffering from glanders showed marked agglutination in ten minutes in a dilution of 1 in 20 in hanging-drop preparations. In test-tube experiments, using dilutions of 1 in 10 and 1 in 20, a change was observed in six hours and sedimentation was complete in 24 hours. Several samples of normal human serum did not show the reaction but it was given by four cases of typhoid fever and by antidiphtheric serum.[2] Wladimiroff, using bouillon cultures, emulsions of bacilli in bouillon or normal salt solution, and insemination of the bacilli in a sterile mixture of broth and the blood to be tested, in a series of observations obtained a positive reaction with a dilution as high as 1 in 300 from the serum of non-glandered horses and a thoroughly characteristic reaction with 1 in 1600 from some horses with glanders. Cabot reports that Bourges and Méry found that the serum of guinea-pigs inoculated with glanders showed after three hours in the thermostat with 1 in 10 dilution clumps which were very different from anything that could be obtained from normal serum. Two horses affected with acute glanders reacted at 1 in 1000 and 1 in 2000 respectively. Another horse with chronic glanders and a fourth in an acute exacerbation of a chronic affection showed a potency of 1 in 1000 in their sera; these results were all obtained by the microscopic test at room temperature and within half an hour. The serum of sound horses had no clumping action on the glanders bacillus. The serum of horses immunised against diphtheria or against tetanus often clumped the glanders bacillus at 1 in 50 or higher dilution and "un cheval fébricitant" showed reaction at dilutions as high as 1 in 300. They propose 1 in 500 as the proper standard test for glanders in horses. Reaction obtained with less dilution they consider unreliable. Muir and Ritchie, commenting on Dr. McFadyean's later experiments, say that in the great majority of glandered horses a 1 in 50 dilution of the serum produces marked agglutination in a few minutes, whilst in the great majority of non-glandered animals no effect is produced under these conditions. Exceptions occasionally occur in both directions if the test is performed in the ordinary way and a more delicate and reliable method is to grow the bacillus in broth containing a small quantity of the serum to be tested. Bourges and Méry[3] tested the serum of 30 horses which were afterwards slaughtered and were proved to be free from glanders and they found that, as a rule, the blood would give an agglutinative reaction with a culture of bacillus mallei with a dilution of 1 in 200; in some exceptional cases reactions were obtained with dilutions of 1 in 300, 1 in 400, and 1 in 700. With glandered horses a reaction was usually obtained with a dilution of 1 in 300 or 1 in 500—sometimes with 1 in 1000. On the other hand, the serum of [illegible] fail to give the specific reaction [illegible] as 1 in 200. The authors conclude that if the reaction occur with a dilution of 1 in 300 or more the presumption is that the horse is glandered but that there is no certainty and that agglutination with a dilution up to 1 in 300 only does not necessarily imply that a horse is not glandered.

It may be said that the serum reaction has been found useless for the diagnosis of glanders in horses and we have the far better mallein test. The diagnostic value of the serum reaction in human glanders has yet to be shown. The matter is of greater importance because the mallein test is not available.

I am indebted to Dr. J. Biernacki for permission to investigate the serum reaction in two cases of glanders under his care at Plaistow Hospital in the laboratory of which the work was done. One case had a previous duration of 13 months and the other of six months. The diagnosis in each instance had been verified by guinea pig inoculation. The bacillus used for the tests was one which had been grown saprophytically for several months; it was obtained from St. George's Hospital but its previous origin I could not trace. An emulsion of bacilli was made from a growth on sloped glycerine agar by half filling the tube with previously boiled normal salt solution and gently agitating for a few minutes. In one series of observations a 36 hour culture was used and the serums and emulsion were mixed on a slide and covered by a cover-glass. Serum from the case of six months' duration was diluted with nine times its volume of normal salt solution and then 10 of bacterial emulsion were added, making a dilution of 1 in 20. Serums from two diphtheria patients were treated in the same way and a control without serum was also made. The preparation containing the glanders serum, when observed immediately after, showed some bacilli adhering together in twos and threes; after half an hour clumps of up to a dozen bacilli were present in many fields, but even after two and a half hours more bacilli were free than clumped. A repetition of the experiment gave a like result. The control without serum showed no clumping. The two preparations containing serum of diphtheria patients showed immediate and well-marked clumping. The reaction was almost complete in 15 minutes, very few bacilli being left between the clumps. Dilutions of 1 in 20 and 1 in 15 were made with serum from the other case of glanders, using a culture five days old and hanging-drop preparations. Controls were made with diphtheria antitoxin 1 in 10 dilution and with emulsion of bacilli without serum. In the preparation containing diphtheria antitoxin clumping occurred immediately and in an hour was practically complete. The two preparations from the cases of glanders could not be distinguished from the control which remained almost unchanged even after two hours. Further, it was noticed that diphtheria antitoxin, 1 in 20, caused large clumps to form in less than 15 minutes and clumping of almost all the bacilli in half an hour. Serum from a normal human subject, 1 in 10 dilution, caused a few clumps to form in half an hour without the clearing of the field between the clumps. Serum from a case of typhoid fever, 1 in 20 dilution, caused clumps to form in less than 15 minutes.

The following sedimentation tests were performed. One part of glanders serum was diluted with 109 parts of normal salt solution and 110 parts of emulsion of glanders bacilli in normal salt solution were added. The same was done with two samples of serum from diphtheria patients. When observed ten hours afterwards the glanders specimen showed definite sedimentation, the others had not. A repetition of the experiment gave the same result and a dilution of glanders serum 1 in 505 also gave it. Typhoid and normal serum showed no sedimentation but serum from both cases of glanders did so. The glanders serum could be differentiated from the others in about four hours, but the reaction became more obvious later, and three observers were able to pick out the unmarked tubes without hesitation. Again, 11 tubes containing blood were numbered and given to me, another person keeping a key; they included blood from one normal person and two enteric fever, two scarlet fever, two glanders, one tuberculosis, one mixed scarlet fever and diphtheria and two diphtheria cases. Dilutions of 1 in 505 were made at night and the two glanders specimens were picked out from the others without difficulty in the morning. In another experiment samples of blood from two cases of enteric fever, two of scarlet fever, two of diphtheria, two of variola, two of glanders, and from two normal persons were numbered and given to me. Dilutions of 1 in 220 were made, when four tubes showed sedimentation. Dilutions of 1 in 505 were then made in these four cases; all showed sedimentation and the experiment was not then carried further. These four cases included the two cases of glanders, one case of variola, and one of scarlet fever. Some further experiments, in which the scarlet fever and variola cases were compared with the glanders of six months' duration, showed that in dilutions of 1 in 1000 there was sedimentation in all, but it appeared sooner and was more complete in the glanders specimen. With dilutions of 1 in 2500 the glanders specimen showed a distinct reaction in 12 hours and the others did not show it. The other glanders case was tested at another time and showed a distinct reaction in dilutions of 1 in 2200. The above specimens of blood were collected from the cleaned ear. No precautions were taken to insure sterility of the leucocytometer pipettes or sedimentation tubes, though the salt solution was previously boiled. The fact that sedimentation was generally visible in six hours and at room temperature was held to obviate the necessity for sterility. Some serums mentioned above as showing well-marked agglutination by the microscopic test were readily differentiated from the glanders serum by the macroscopic test.

A CASE OF ACUTE LYMPHATIC LEUKÆMIA.

By H. SAVORY, M.B., B.C. CANTAB.,
ASSISTANT PHYSICIAN, BEDFORD COUNTY HOSPITAL.

ACUTE lymphatic leukæmia is so rare and so few cases have been published in the English journals that I venture to place this case on record. Da Costa,[1] in 1902, stated that probably fewer than 75 authentic cases had been published at that time. None were published in England before 1898, when Dr. Rose Bradford and Dr. Batty Shaw[2] described five cases. Among others a case published by Rocaz[3] presents a remarkable similarity to the present case, as also does one recorded by S. Welt Kakels,[4] in a child, aged 18 months, where the per centage of lymphocytes was the same, 96 per cent of all leucocytes, but the small lymphocytes were three times as numerous as the large ones. This case also ran an acute course.

The patient was a boy, aged four and a half years. In July, 1902, he was circumcised and as far as his parents observed was in good health till the following December, when he became peevish, out of sorts, and off his food. On Dec. 9th he walked with his parents to my house, a distance of nearly a mile. I found him a trifle pale, with furred tongue, foul breath, a few impetiginous sores round his mouth, a rather quick pulse (90), but no bruit or other physical signs of anæmia or other disease. I prescribed an aperient and some citrate of iron. A week later he again walked to my house to report progress; I mention this to show that the child wa[illegible] though he must then [illegible] disease which was to p[illegible] visit I found the pa[illegible] dyspnœa and some sor[illegible] whilst several of his teeth were decayed and abscessed; he also had adenoids and hypertrophied tonsils and was a mouth-breather; this might have been due to swelling of lymphoid tissue. I advised rest in bed and made an attempt to obtain a less septic condition of his mouth. When I examined him in bed I found a few very slightly enlarged glands in the right axilla and above the right clavicle but none elsewhere. No enlargement of his liver or spleen could be made out then or at any subsequent time. His bones were not tender and I failed to make out any enlargement of his thymus. He was not wasted, his skin was sallow and very rough, but there were no eruptions of any kind. There was no œdema of his extremities. His urine was pale and free from albumin. As he did not improve under treatment, but got paler and more breathless, I made an examination of his blood which at once cleared up the diagnosis. The hæmoglobin, as estimated by Haldane's hæmoglobinometer, was 35 per cent. There were 2,157,000 red corpuscles and 356,000 leucocytes per cubic millimetre, the red being 43 per cent. of normal and the colour index $\frac{8}{10}$. The leucocytes were about one to every 6 erythrocytes. Subsequent counts were rendered valueless by the extremely nervous condition of the patient, but in some of the later stained slides the ratio seemed even lower. Slides stained with eosin and hæmatoxylin showed the red cells practically normal and only two nucleated red cells were observed in counting 611 white cells; both were normoblasts. The leucocytes gave the following differential count: polymorphonuclear neutrophiles, 12,282, 3·45 per cent.; large and small lymphocytes, 342,009, 96·07 per cent.; eosinophile leucocytes, 1174, 0·33 per cent; and myelocytes, 569, 0·16 per cent. The large lymphocytes greatly predominated but there was no line of demarcation between the large and the small, so they were counted together; the majority seem about from 12 to 14 micromillimetres in diameter. During January, 1903, the patient gradually assumed a lemon-coloured aspect and his sclerotics a pearly whiteness, his dyspnœa increased, and he had fever often reaching 104° F. and seldom being less than 100°. His pulse became rapid and often could not be counted, but there were no hæmic murmurs over his cardiac area. He did not perspire visibly. His gums continued sore and they bled readily, producing a very foul condition in his mouth. He had several attacks of epistaxis and there were numerous hæmorrhages into his retinæ but no subcutaneous or arthritic bleeding, no hæmatemesis, melæna or hæmaturia, and no swellings which could suggest chloroma. At various times I administered arsenic, mercury with chalk, salol, and oxygen, but no remedies appeared to have any effect, and he became drowsy, had occasional violent attacks of convulsions, and died on Jan. 29th, which was seven weeks after first coming under medical observation. A post-mortem examination was unfortunately refused.

Osler[5] in his last edition states that he had only 24 cases of leukæmia in his wards and of these 15 were splenomedullary and nine lymphatic; of these nine three only ran an acute course. According to the same authority the large lymphocytes are the more characteristic of the acute form and the small lymphocytes of the chronic one. The lymphocytes in my case were chiefly from 12 to 14 micromillimetres in diameter and as the patient died in seven weeks the nomenclature seems orthodox.

A CASE OF OVARIAN "FIBROID" TUMOUR REMOVED BY POSTERIOR COLPOTOMY; SUBSEQUENT PREGNANCY.

By JOHN PHILLIPS, M.A., M.D. CANTAB.,
F.R.C.P. LOND.,
OBSTETRIC PHYSICIAN, KING'S COLLEGE HOSPITAL; FELLOW OF, AND LECTURER ON PRACTICAL OBSTETRICS IN, KING'S COLLEGE; SENIOR PHYSICIAN, BRITISH LYING-IN HOSPITAL.

MUCH attention has recently been paid to the study of fibroid tumour of the ovary and the elaborate paper by Dr. Reuben Paterson, entitled "A Consideration of Ovarian Fibromata based on a Study of Two Recent Cases and 82 collected from the Literature,"[1] tells us all that is practically known on the subject. As it seems important to put on record as fully and accurately as possible any additional instance of the kind I have ventured to relate the following case as bearing on the matter under consideration.

A woman, aged 28 years, who had been married a year, considered herself to be four months pregnant. Up to that time nothing beyond amenorrhœa, morning sickness, and

---

[1] American Gynæcology, July, 1902, p. 45.

some mammary distension had attracted her attention. She was then suddenly seized with violent pain in the right iliac region after dinner in the middle of the day. She had been doing nothing to account for its occurrence. She was very sick and was obliged to go to bed; there was no hæmorrhage. She was seen by Mr. C. W. Grant-Wilson who found a fixed swelling of the size of the closed fist blocking the upper third of the pelvis. The uterus, showing all the physical signs of a four months gestation, was pushed upwards and forwards by the growth which was apparently attached to the lower and posterior segment. The conjugate diameter of the pelvic inlet was reduced to a size just sufficient to pass two fingers by the obstruction. Under an anæsthetic an attempt was made to push up the growth above the brim, but this failed and as the patient declined to submit to a Cæsarean section induction of abortion was performed and the uterus was emptied. Three weeks subsequently the growth was found to be somewhat smaller in size, fixed, and attached to the lower uterine segment. A diagnosis was made of subserous fibroid tumour and it was decided to attempt its enucleation by a vaginal operation. On April 14th, 1900, the patient was anæsthetised and placed in the lithotomy position. The cervix was pulled downwards and forwards by means of a vulsella. A transverse incision was then made into Douglas's pouch and several spouting vessels were secured. On incising the peritoneum about a tablespoonful of clear fluid escaped; on inserting the finger the tumour was felt closely attached to the posterior and right wall of the uterus and the posterior portion of Douglas's pouch. The adhesions were gradually broken down and a lump of creamy white colour was freed; a vulsella was attached to the lower portion and it was delivered slowly through the vaginal opening. The tumour was found to be attached by a pedicle consisting of right broad ligament and Fallopian tube to the right uterine cornu. This pedicle was ligatured and the mass was cut away. The edges of the vaginal wound were brought together and a small gauze drain was inserted into the peritoneal cavity. Convalescence was quite uneventful. A few months later the patient became pregnant and was delivered easily and naturally of a full-time child. The puerperium was normal in every way. She has since remained quite well.

Description of parts removed.—Hanging from the outer end of the Fallopian tube was a pyriform swelling which in section was seen to be made up partly of the remains of the ovary and partly of new growth. The length of the swelling was three and a quarter inches, the width being two and a half inches; the lower two and a half inches were occupied by a fibroma and in the upper portion which formed the apex of the tumour were seen the remains of the ovary containing a Graafian follicle and also a small cyst. Microscopical examination of the new growth showed it to consist of pure fibrous tissue.

I have been enabled to find three other cases of pregnancy complicated by ovarian fibroma. Kleinwächter's patient[2] was aged 31 years and a primigravida. Nothing had occurred to excite attention during the pregnancy. At labour the tumour, of the size of a clenched fist, was felt apparently arising from the anterior surface of the sacrum; no descent of the head could take place. Cæsarean section was performed without any difficulty but the patient died 24 hours afterwards from acute peritonitis. At the post-mortem examination the right broad ligament was found stretched and the ovary was occupied by a hard, solid tumour of the size of a fœtal head lying at the back of the uterus; calcification was going on in its substance.

Henry Carstens[3] records a case of successful removal of a fibroma of the right ovary during pregnancy. He could find no similar instance on record up to 1889. The patient was aged 26 years. She had been married four years and had had no children or miscarriages. For a year she had noticed trouble with micturition, there being a frequent desire to evacuate the bladder and also a partial loss of power of the sphincter vesicæ. At an examination made under chloroform a hard tumour filling up the right and anterior part of the pelvis with a two months gestation was found. When three months pregnant the abdomen was opened and a right ovarian fibroid was removed after separating adhesions with the bladder and the bowel. No mention is made of the presence or absence of ascites. The left ovary was left *in situ* as it was healthy. At the time of recording the case the patient was seven months pregnant and probably a living child was born. The tumour was hard and nodular, 20 centimetres long, and 12 centimetres in diameter. Microscopical examination showed it to consist of purely fibrous structure. "The ovary had entirely disappeared in the growth." Whitridge Williams[4] mentions another case which came under his care in which he operated during pregnancy and removed a calcified ovarian fibroid. The patient did well and was delivered at term.

The above cases seem to confirm all that has been written on the subject by Paterson.

The vaginal operation was performed under a misapprehension as to the nature of the growth but it illustrated how much more easily such a tumour can be removed by the vaginal route as compared with the abdominal. Indeed, had I been aware of what I actually had to deal with I should not have altered the method of procedure.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

THE MEMORIAL HOSPITAL, BULAWAYO.

(1) A CASE OF INTERSCAPULO-THORACIC AMPUTATION; AND (2) A CASE OF CÆSAREAN SECTION.

(Under the care of Mr. W. G. CLARK.)

CASE 1. *Interscapulo-thoracic amputation in a Matabele woman for a rapidly growing sarcoma of the head of the humerus, involving both the scapula and the clavicle.*—The patient, aged about 18 years, was admitted to hospital on Oct. 17th, 1903, suffering from a sarcomatous growth of the left shoulder. The growth was said by the patient and by the white man on whose farm her husband was working to be of only three months' duration and to have been treated in the usual Kafir way by incisions. Two days previously to admission, in showing how large a weight she could lift, the humerus broke.

On Oct. 19th chloroform was administered and with the assistance of Mr. W. T. Pauling Mr. Clark removed the outer two-thirds of the clavicle, the arm, and the scapula. The clavicle having been bared of periosteum for the greater part of its length the chain-saw was used to divide it at the junction of the inner and middle thirds. The outer part of the clavicle was then divided by the hand-saw at the junction of the outer and middle thirds. After dividing the periosteum the main vessels were ligatured, and this part of the operation presented considerable difficulty, owing to the great size of the vein, the prominence of the tumour, and the overlapping of the artery by the vein. The artery was with some considerable trouble secured first. Although there was a history of loss of flesh the ligature of the vessels was also rendered troublesome by the amount of adipose tissue, which is always considerable in the young Matabele girl. It was necessary to fashion flaps entirely with reference to the size of the growth, but as it happened there was little difficulty in bringing them together. The operation lasted one and three-quarter hours. Recovery was uneventful, the highest temperature reached being 100° F. and this was clearly due to mastitis of both breasts. The wound when dressed on Oct. 26th was quite dry and almost healed.

CASE 2. *Cæsarean section in a Matabele woman; recovery.*—An achondroplasic dwarf was admitted to hospital on Sept. 12th, 1903, from the mission station at Hope Fountain, being at the end of her eighth month of pregnancy. At birth she was an infant above the normal in size. When her growth failed she was taken care of at the mission station. Eight years previously she was attended in her only other pregnancy; the infant failed to be delivered by nature and the after-coming head was retained for 24 hours before a medical man could be obtained The head was delivered by "irons" Recovery resulted with, however, a vesico vaginal fistula No further history was obtainable, but from the absence of lineæ gravidarum it seems certain that her confinement took place before term The following was her condition when admitted She was 3 feet 11 inches in height She had a true conjugate of two and a quarter inches The abdomen had the appearance of a full term pregnancy owing to the small space between the ensiform cartilage and the pubes Urine leaked into the vagina and it was impossible to pass a catheter from the urethral orifice into the bladder By the speculum an opening into the bladder could be distinguished It was decided to operate almost immediately for the following three reasons —First, the fear of infection from the urethra should the cervix become too dilated; secondly, the comparatively small space between the ensiform cartilage and the pubes, and thirdly, the habit that natives have of changing their minds and so placing themselves beyond the reach of medical aid Delivery per vias naturales was manifestly impossible

[3] Transactions of the American Association of Obstetricians and Gynæcologists, vol. ii., 1889, p. 151.

[4] American Gynæcological Transactions, vol. xxvii., 1902, p. 293.

Operation was performed on Sept 17th Accordingly chloroform was administered and with the assistance of Mr Pauling Mr Clark performed laparotomy Mr Clark was prepared to perform Porro's operation if necessary but he intended to perform Sanger's operation if possible With some difficulty he was able to make a sufficiently long incision to turn the uterus out of the abdomen This course was pursued in case there should be a placenta prævia and there was only one assistant. On examination the placenta appeared to be felt near the left cornu of the uterus, but this appearance proved to be completely fallacious On incising the uterus in the middle line Mr Clark twice cut into the placenta and there was a considerable amount of hæmorrhage which was checked with sponges He therefore incised the uterus at and just below the fundus, ruptured the membranes, and delivery was accomplished in a few seconds The child cried at birth and the uterus contracted well, the placenta being completely detached in the course of delivery The uterus was readily stitched in the usual way but during this part of the operation there was a great tendency to hæmorrhage from the placental site and the elastic ligature round the uterus proved extremely useful An attempt to pass a drain through the cervix into the vagina failed, although previously to the operation the cervix had been tested and the uterus was showing good contractions The tubes were ligatured and a piece of each was excised The operation occupied one and a quarter hours The child, who weighed three and a half pounds, died three hours after birth The recovery of the mother was uneventful. The highest temperature reached was 99° F The wound when dressed on the tenth day was quite dry The uterus appeared to be adherent to the parietes The lochia were moderate in amount

The following are the measurements obtained Height, 3 feet 11 inches Length of leg from the anterior superior spine to the internal malleolus, 19 inches Dimensions of the pelvis conjugate vera, 2¼ inches, diameter of Baudelocque 5½ inches, distance between anterior superior spines, 7⅞ inches, distance between iliac crests, 8½ inches, and intertrochanteric, 9⅝ inches

Remarks by MR CLARK —During the past 18 months an average of 40 natives have been under my care daily and Case 1 is the only malignant tumour that I have seen in the native race of Matabeleland The medical men who have been accustomed to treat the natives for some years also testify to the rarity of malignant disease among them, so much so, that they even connect its occurrence with the introduction of civilisation The girl was five months pregnant at the time of operation, but the pregnancy remained undisturbed and convalescence was rapid The growth was undoubtedly a myeloid sarcoma commencing in the head of the humerus

The interest in Case 2 lies chiefly in the condition occurring in a Matabele woman In this race it seems to be an invariable rule to destroy any individual deformed at birth Further it appears that any dwarf or deformed person is similarly corrected out of existence Whether the custom prevails to the same extent since the British occupation of Rhodesia is a doubtful point That the present individual should exist depends on the facts of her appearing to be normal at birth and later having been removed to a mission station The Matabele race numbers, roughly speaking, a quarter of a million and it is *most* exceptional to meet with any dwarf or other kind of deformity among its members, apparently for the above reasons I have met with no case of achondroplasia, or any sign of cretinism, or any other cause of diminutive stature amongst them, although my opportunities have been ample for so doing

As far as the operation is concerned, firstly with reference to the condition of placenta prævia, I was enabled to deal with this with the greatest ease owing to the uterus having been turned out of the body, which method I resorted to owing to a somewhat similar experience which I had when intern midwifery assistant to Dr F H Champneys On that occasion I saved the life of a child by a post mortem Cæsarean section, meeting then with a placenta prævia, when the hæmorrhage was enormous I was duly impressed with the fact that there might be great difficulty in dealing with such a case during the life of the mother I also experienced the advantage of the elastic band, because bleeding tended to continue during the physiological relaxations of the uterus The band, however, was never urgently needed Secondly, I found no difficulty in avoiding the bladder in spite of the limited room and the impossibility of passing a *bladder sound* *Thirdly, I was impressed with the ease* of rapid delivery without soiling the peritoneum which required neither sponging nor draining

It seems almost superfluous to add that cases of difficult labour are practically unknown amongst the natives of Matabeleland and Mashonaland

OPHTHALMOLOGICAL SOCIETY

Proptosis —Asthenopia —Eye Symptoms of Rheumatoid Arthritis —Tuberculosis of the Choroid —Exhibition of Specimens and Cases

AN ordinary meeting of this society was held on Jan 28th, MR CHARLES HIGGENS Vice President, being in the chair

Mr W H

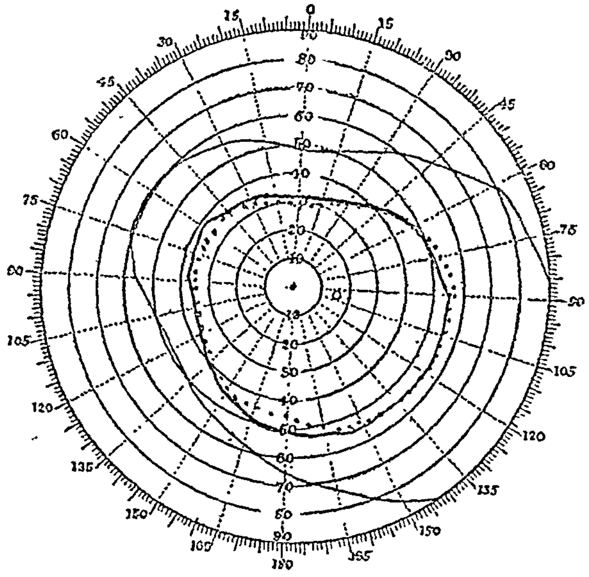
two cases

being a man

ing in the right temporal region and protrusion of the eyeball He was treated with potassium iodide but without much relief The vision was reduced to counting fingers at 12 inches there was slight ptosis the pupil measured four millimetres in diameter and was inactive, the optic disc was pale, and there was a discharge from the nostril An incision was made into the swelling and dead bone was discovered This gave slight relief but the pain soon returned and Mr H J Waring then undertook a very extensive operation and removed a great deal of necrosed bone including the great wing of the sphenoid The patient recovered from the operation and was much benefited The second case was that of a woman who had normal acuteness of vision when first seen but subsequently developed retrobulbar neuritis and supraorbital neuralgia The symptoms increased proptosis was developed, and tumour of the optic nerve was diagnosed Sir Victor Horsley operated and found the growth which was proved to be an endothelioma The patient was much relieved Mr Jessop referred to other cases and emphasised the great relief afforded by the operations

Mr G T BROOKSBANK JAMES read a paper detailing a plan of treating some cases of Asthenopia He had noticed how rare it was to see myopia in watchmakers and those who used a single eyeglass for magnifying their work, applying the same principle to other cases he had come to the conclusion that the development of myopia might be arrested by similar means He mentioned the case of a patient who had — 1 5 D myopia and for this he ordered a glass of + 1 5 to be used for one eye only so that convergence might be prevented The myopia did not increase during many months while using this method though it increased 0 5 when ordinary glasses were used —Mr C A WORTH thought that in cases in which pain and fatigue were prominent hyperphoria was present —Mr N BISHOP HARMAN did not consider that the mere closing of one eye would prevent convergence when looking at a near object and thought it would much interfere with education if this plan were adopted

Mr W M BEAUMONT (Bath) read a paper on the Eye Symptoms of Rheumatoid Arthritis with especial reference to the Field of Vision. He said that whether they accepted the bacillary view of Dr G A Bannatyne and Dr Wohlmann or the cerebro-spinal toxæmia theory of Dr. Llewelyn Jones there was much in the pathology of this disease which was obscure. After alluding to the transient obscurations of vision, to the ephemeral palsies of the external ocular muscles, and to the frequency of conjunctival, and even corneal, anæsthesia in rheumatoid arthritis, he referred more particularly to the decided contraction of the field of vision which often occurred in that disease. In a compound chart made up of the average field of 24 male patients suffering from rheumatoid arthritis he showed the similarity of the field to that of 50 women suffering from the same disease (vide chart). These average charts were arrived at by what he believed to be a novel method. The number of degrees from the fixation point outwards was noted in each of the 24 male patients, added together and divided by 24, in order to get the mean. The other meridians were then treated in a similar way and so an average field of vision was constructed. That of the 50 females cases was constructed in the same manner. The uniformity of the fields of vision in male and female, he thought, quite excluded hysteria as a factor in the causation of the contraction. There were no central scotomata in rheumatoid arthritis, there was no evidence of optic nerve atrophy, and there was not usually more than a proportionate contraction of the colour field. He remarked upon the Raynaud-like symptoms which sometimes occurred in rheumatoid arthritis, as pointed out by Dr. Llewelyn Jones, and he said that Dr. Samuel Lodge had observed contraction of the field of vision in connexion with Raynaud's phenomena. It might be that the small field of vision in rheumatoid arthritis was due to the syncopal condition of the terminal vessels of the retina. Diagrams of the field of vision in rheumatoid arthritis were shown in which decided expansion occurred during the inhalation of nitrite of amyl, whereas in healthy persons no such expansion took place.



Mr. J. R. LUNN described a case of Tuberculosis of the Choroid. The patient, who was six years of age, was suffering from symptoms of general tuberculosis and was in a typhoid condition. There was a discharge from the left ear. Optic neuritis was present and there was a swelling in the choroid. In spite of the disease the child got quite well, but the oval area in the choroid was still present though the optic neuritis had subsided. He thought the case was doubtless tuberculous.—Mr. JESSOP mentioned a case of allied character.

The following cases and specimens were shown:—

Dr. S. JOHNSON TAYLOR: A Swelling of Unusual Size, probably inflammatory, in the Ciliary Region.

Mr. E. TREACHER COLLINS: An Unusual Superficial Circumferential Opacity of the Cornea, symmetrical in the two eyes.

Mr. G. W. THOMPSON: An Unusual Form of Central Choroiditis in a young man.

Mr. G. W. ROLL: Unusual Changes in the Macular Region.

Dr. D. MOWAT: Paralysis of the Inferior Recti Muscles.

Dr. RAYNER D. BATTEN: Subretinal Hæmorrhages.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Concealed Accidental Hæmorrhage.—Thrombosis of the Superior Mesenteric Vein.—Puerperal Eclampsia.—Uretero-lithotomy.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Jan. 22nd, Mr. O. RICHARDSON, the President, being in the chair.

Mr. G. P. ANNING related a case of Concealed Accidental Hæmorrhage. The patient was a married woman, aged 35 years, who was on April 9th, 1903, delivered of a seven and a half months female child, stillborn; this was the eighth pregnancy. It was a vertex presentation. The uterus was almost as large as at full term; it was hard, tender, and bossed over the placental area. No labour pains were present. The os was undilated; there were severe pain, restlessness, and vomiting. The pulse was 90. Active treatment was deferred for 18 hours. The pulse was now 120 One-tenth of a grain of strychnine was administered. The membranes were ruptured with Lister's sound. Labour pains occurred an hour later. The os was fully dilated in four hours, the pulse being 144. Chloroform was given to full anæsthesia and forceps was applied. No hæmorrhage took place until the placenta was expressed. Retroplacental clots were present which weighed two pounds. No saline infusions were used. The pulse rate on the following evening was 111 and the temperature was 100·8° F. The patient recovered. convalescence being normal. The differential diagnosis of the varieties of accidental hæmorrhage was discussed. The treatment was as follows: 1. Where there were vigorous contractions and the os was dilating, by rupture of the membranes, introduction of the Champetier de Ribes's bag, and delivery by forceps under chloroform. 2. In severe cases where the uterus was paralysed, by plugging the vagina and the application of a binder and a perineal bandage as described by W. J. Colclough.—Dr. J. B. HELLIER, Dr. C. OLDFIELD, and the PRESIDENT discussed the paper and Mr. ANNING replied.

Dr. E. WARD related a case of Thrombosis of the Superior Mesenteric Vein in which the symptoms simulated intestinal obstruction.

Dr. A. A. MCNAB read a paper on Puerperal Eclampsia illustrated by nine cases without a single death. He advocated the administration of chloroform with digital dilatation of the os and speedy delivery as soon as labour commenced; otherwise he was against operative treatment. In a case where chloroform was inadmissible he administered chloral and bromide per rectum. He thought that rectal saline injections were to be preferred to intravenous infusion.—Dr. S. JOHNSTON, Mr. J. W. DRAPER, and Dr. HELLIER took part in the discussion and Dr. MCNAB replied.

Mr. J. F. DOBSON read notes of a case of Uretero-lithotomy. The patient, a man, aged 25 years, had suffered from renal colic for four months and during the later attacks the kidney had become enlarged. Hæmaturia and pyuria were absent but the urine contained albumin. The patient was thin and on palpating the abdomen a calculus was felt in the ureter just over the common iliac artery. Retroperitoneal exposure of the ureter was made by an incision internal to the spine of the ilium and the calculus, which was rough, angular, and imbedded in the wall of the ureter, was extracted through a longitudinal incision one centimetre in length. The permeability of the ureter was assured by passing a bougie up into the kidney and down into the bladder; no sutures were placed in the ureter but the wound was drained. The escape of urine ceased on the fifth day and the patient made a good recovery.—Dr. WARD and Mr. H. COLLINSON discussed the paper and Mr. DOBSON replied.

The following cases and pathological specimens were shown:—

Mr. E. HAWKESWORTH HACKETT: A Skiagram of a piece of steel removed from the eye seven days after the accident; also the piece of steel removed.

Mr. B. G. A. MOYNIHAN: (1) A series of specimens from cases of Cholecystectomy; and (2) a specimen of Imperforate Ileo cæcal valve.

Dr. T. CHURTON: (1) A case of Recovery from Spinal Meningitis in which Lumbar Puncture was performed and pus cells were found in a drop of the fluid; and (2) a case of Adiposity with Nervous Symptoms.

Dr. WARD: (1) Parts from a case of Gastric Ulcer with Severe Hæmatemesis in which death from recurrence of hæmorrhage ensued 36 hours after gastro-enterostomy; and

(2) a case in which the Staple Operation for Femoral Hernia had been performed.

Mr. H. SECKER WALKER: Some Ophthalmic Cases.

Dr. A. G. BARRS: A case of Cirrhosis of the Liver occurring in Diabetes.

Mr. COLLINSON: A case of Double Congenital Equino-varus treated by Cuneiform Osteotomy.

Mr. G. CONSTABLE HAYES: Some Skiagrams.

Dr. HELLIER: (1) Ruptured Tubal Pregnancy; and (2) the Bossi-Trommer Uterine Dilator.

Mr. R. LAWFORD KNAGGS (with Mr. CONSTABLE HAYES): A case of Atrophic Scirrhus of the Breast under treatment by the X Rays with amelioration of the condition.

Dr. E. F. TREVELYAN: A case of Peculiar Tremor with an involvement of speech in an elderly woman.

Mr. H. LITTLEWOOD: (1) a Fracture of the Femur after five and a half weeks' treatment with massage; and (2) Gangrenous Vermiform Appendix with large masses of fat in the mesentery.

THERAPEUTICAL SOCIETY.—A meeting of this society was held in the Apothecaries' Hall on Jan. 19th, Sir W. Thiselton-Dyer presiding.—Professor J. B. Farmer spoke on Some New Discoveries respecting Cancer, saying that the causation of cancer by parasites or stray cells was not proved, but that he, with Mr. J. E. S. Moore and Mr. C. E. Walker, had found that the development of cancer cells differed from that of the cells of other tumours and closely resembled that of reproductive cells. In both animals and plants the nuclei of the somatic cells divided longitudinally into rods or chromosomes, but reproductive cell nuclei divided more transversely into oval or ring-like chromosomes, forming only half the number of the chromosomes of the somatic cell nuclei, and cancer cells divided like the latter, and similarly had the power of destroying any somatic cells in contact with them, as occurred in the embryo sac of plants. This division was found in some cells of all malignant growths but not in any benign tumour cells. The somatic [illegible] ductive cells by [illegible] s were not yet [illegible] The frequent [illegible] ths while they [illegible] characteristic heterotype mitosis; they were probably related with nutritional and other disturbances that were known to affect similarly the nuclei of normal tissues.—Dr. T. N. Kelynack then spoke of the Hygienic Treatment of Pulmonary Tuberculosis based on inspection of many establishments. He indicated how pioneers like Parrish, Bodington, and Richardson had anticipated hygienic measures in the treatment of phthisis and also the need for a systematised "after-cure" of consumptives. He showed that wide differences existed in clinical methods and therapeutical practice in sanatoriums and urged that efforts should be made to secure scientific uniformity in their clinical procedure and combination in investigation and a system of recording returns which would allow of a comparison of results. In sanatorium management it was most desirable that a narrowing of outlook should be avoided and a scientific spirit strictly maintained.—Dr. J. Gray Duncanson then spoke of the Suprarenal Gland Products and described the medicinal preparations of them. Dry powders were best for internal administration and liquid extracts for hypodermic use. The active principle adrenalin, first isolated by Takamine, a Japanese chemist, has the empirical formula $C_{10}H_{13}NO_3$. Dr. Duncanson described the use of the preparations in private practice in ecchymosis and other conditions of the eye and their hæmostatic qualities when applied to a bleeding surface either directly or even indirectly. He warned against their administration in hæmoptysis and diabetes, citing cases which became worse under their use, and he concluded with an appeal for the recognition of suprarenal gland products as therapeutical agents.—Sir W. Thiselton-Dyer, Sir Hugh R. Beevor, Dr. H. D. Rolleston, Dr. Wild, and Dr. C. W. Glassington spoke in the discussions.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—A meeting of this society was held on Jan. 20th, Dr. A. F. Street (Westgate-on-Sea), the President, being in the chair.—Dr. W. S. Hedley read a paper on Physical Therapeutics. He first referred to Professor Dewar's discovery of the presence of helium when examining the gases collected over the King's bath at Bath and to the fact that Sir William Ramsay and Mr. Soddy had seen the spectrum of helium develop in a vacuum tube into which nothing but the radiation and "emanation" of radium had been admitted. Radium, in fact, developed helium by a spontaneous change; and a sample of the deposit from the Royal bath at Bath was found to contain radium in appreciable quantity. Such substances being in a nascent form might help to explain the comparative inefficacy of the waters of certain springs when removed from their source, and the same fact might perhaps supply a reason for the recognised difficulty of making successful artificial imitations of the waters of mineral springs. The radiations of radium were then considered, the "alpha" rays being shown in the spinthariscope and those from polonium on a screen. The bactericidal properties and therapeutical applications of radio-active substances were then considered, and "applicators" for throat, nose, and gynæcological work were shown, as well as thorium, pitchblende, and other plasters made up by Mr. Martindale for the occasion. The "N" or Blondlot rays were then discussed, their place in the scale being apparently between the infra-red of the spectrum and the shortest wave length of the Herzian waves. The therapeutic action of heat was then dealt with as well as light of various colours, and the necessity for the use of the actinometer to secure definite and accurate dosage. The importance of measurement of the quality and quantity of the x rays was also insisted upon and a new method of effecting it by means of a milliampèremeter was demonstrated. High frequency currents were then considered and a reference was made to the tendency to desert the methods of the condensation couch and auto-conduction for bipolar effluvation, the latter being demonstrated.—Dr. A. E. Sansom narrated his experience of the high-frequency currents at Aix and mentioned that a very great authority there thought little of them.—Dr. George Herschell said that he could not agree with Dr. Sansom that the results of high-frequency applications were mainly due to suggestion. Administration of a current from a small solenoid with a spark gap in the circuit gave rise to muscular contractions equalling those produced by the induced current or by the Morton current. There could be no suggestion about that. The effect upon hæmorrhoids also was a visible one for a pile an inch in diameter might shrink to half the size as the result of two or three applications of a condenser electrode.—The President, Dr. E. Symes-Thompson, Dr. Joseph Groves, Dr. Septimus Sunderland, Dr. Sansom, Dr. Leonard Williams, Dr. J. Braithwaite (Buxton), and Dr. C. H. Gage-Brown also took part in the discussion.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.—The quarterly meeting of this society was held on Jan. 29th, Mr. J. Bark of Liverpool, the President, being in the chair.—A case of Intermittent Nasal [illegible] Progressive Deaf- [illegible] President said [illegible] in connexion [illegible] with Mr. Collier's paper later.—Dr. W. H. Kelson showed a case of Laryngitis in a girl.—Dr. J. Dundas Grant asked if there were any signs of hysteria and remarked on the enlarged tonsils and ventricular band phonation.—Dr. J. E. McDougall (Liverpool) suggested that the tonsils should be removed.—Dr. Kelson, in reply, said that he intended to remove the tonsils.—Mr. W. Stuart-Low showed a series of cases of Aural Sepsis treated by means of kelvolin vapour and the local application of pure kelvolin.—The President regarded these cases as very satisfactory and encouraging.—Dr. Dundas Grant, Mr. E. D. Vinrace, Dr. W. Jobson Horne, Dr. Kelson, and Mr. W. J. Chichele Nourse discussed the cases.—Mr. Stuart-Low, in reply, thanked the President and Fellows for their kind reception of the subject. All the cases shown had been under the usual methods, some for years before coming under the treatment. Two of the cases shown were Dr. P. S. Jakins's patients and both were instances of intractable discharge. Cultures were always taken before using the vapour and then it was pushed until the culture was negative. There was no doubt about the germicidal power of kelvolin vapour, even the staphylococcus succumbed to its influence. There had been no failures but when many granulations were present shielding the seat of the mischief the treatment was necessarily more prolonged.—Mr. Stuart-Low also showed a case of Nasal Polypi in a boy seven years of age. Professor Hajek of Vienna had visited Dr. Dundas Grant's clinic and seen this case. He had never seen polypi in so young a subject and said that sarcoma was likely.—Dr.

A. Wylie showed a case of Primary Hard Sore on the lip of a woman.—The President said that it was the first he had seen.—Dr. Jobson Horne said that such cases were uncommon but he had seen three in five years.—Dr. Wylie showed a case of Neoplasm, probably malignant, of the Œsophagus causing Paralysis of both Vocal Cords.—Dr. V. H. Wyatt Wingrave showed a case of Laryngeal Disease (Tuberculosis) in a man, aged 30 years.—Dr. Kelson showed a case of Eruption on the Fauces.—Mr. H. S. Barwell showed a case of Syphilitic Laryngitis —The President showed a case of Growth in the Anterior Commissure above the Vocal Cords.—Mr. Collier then read a paper on Latent or Intermittent Nasal Obstruction.—The President thanked Mr. Collier and said that the discussion on the paper would be taken at the next meeting.

HUNTERIAN SOCIETY.—A pathological evening of this society was held at the London Institution on Jan. 27th, Dr. S. H. Appleford, the President, being in the chair. The following specimens were shown and discussed:—Dr. E. W. Goodall showed the Intestines with a drawing and photograph from a case of Dysentery in a girl, 17 years of age. The relation of acute ulcerative colitis to asylum dysentery and tropical dysentery was discussed.—Dr. W. Langdon Brown stated that the late Dr. Washbourn had failed to find the amœba coli in any of a very large number of cases of dysentery examined by him in South Africa.—Dr. Goodall also showed a case of Ulceration of the Tongue and Pharynx after Measles.—Dr. W. H. Kelson showed a large Mucous Polypus removed from a man whose post-nasal space it had completely filled.—Dr. Henry Russell Andrews showed a very beautiful specimen of a Lithopædion of six years' duration which he had removed from the abdomen with an ectopic gestation of the other tube. He called attention to the remarkable fact that this woman had conceived but twice, each gestation had been tubal, and the first had produced a lithopædion.—Dr. Lewis A. Smith exhibited an Acute Gastric Ulcer which had ulcerated through the coronary artery of a young woman and led to her death by a profuse hæmorrhage. He discussed the importance of recognising whether the ulcer was (1) chronic and indurated, (2) a round ulcer eroding a large artery, or (3) a mere erosion. The second of these was alone suitable for immediate surgical interference with the ulcer itself. Dr. Smith also showed a characteristic specimen of the contracted leather bottle form of Carcinoma of the Stomach. He pointed out the insidious character of the symptoms and the fact that the mucous membrane was not ulcerated in these cases.—Mr. J. H. Targett pointed out that this form of carcinoma found its homologue in atrophic scirrhus of the breast.—Dr. W. H. Kershaw (introduced by Dr. F. J. Smith) and Mr. Hugh M. Rigby showed a specimen of Diaphragmatic Hernia of the Transverse Colon and Omentum into the Left Pleura The aperture resulted from a stab wound two years before. Mr. Rigby strongly supported the view that these herniæ as soon as they were diagnosed should be attacked by the transpleural method.—Mr. Harold L. Barnard showed a specimen of a Hernia into a Duodeno-jejunal Fossa. It was remarkable for the reason that the aperture was to the right of the root of the mesentery, but the sac passed below the superior mesenteric artery into the left. side of the abdomen; and, secondly, because the lower jejunum was the gut strangulated in the sac.

ROYAL MEDICAL SOCIETY OF EDINBURGH.—A meeting of this society was held on Jan. 22nd, Dr. D. C. L. Fitzwilliams, the President, being in the chair.—A paper on Massage by Dr. R Dods Brown was read in his absence by Dr. G. A. Paulin. Dr. Brown classified the various manipulations employed in massage under the four titles, effleurage, pétrissage, tapotement, and friction; and indicated under what conditions one or more of these methods should be employed. In removing effusions—e.g., in sprains—vigorous handling was required and this should be in the direction of the flow in veins and lymphatics; in treating constipation by abdominal massage the direction of the colon was to be followed; while in cases of insomnia massage of the forehead along the lines of the nerve trunks was indicated, and in this case the manipulations must be of the nature of effleurage—i e, very light, stroking movements.—Dr. D. M. Callender read a paper on the Borderland of Gynæcology in which he discussed the differential diagnosis of difficult abdominal cases where a gynæcological condition was one of the possibilities. Ovarian tumours had, for instance, been confounded with renal and splenic tumours and with cases of tuberculous peritonitis. Again, in acute abdominal cases the diagnosis was often extremely difficult between such gynæcological conditions as, on the one hand, ruptured ectopic gestation or an ovarian cyst rendered purulent by twisting of the pedicle and, on the other hand, non-gynæcological conditions like ruptured gastric ulcer, fulminating appendicitis, or strangulated hernia.

Reviews and Notices of Books.

Diseases of the Ear: A Text-book for Practitioners and Students of Medicine. By EDWARD BRADFORD DENCH, Ph.B., M.D., Professor of Diseases of the Ear in the University and Bellevue Hospital Medical College; Aural Surgeon, New York Eye and Ear Infirmary, &c. With 15 Plates and 158 Illustrations in the text. Third edition, revised and enlarged. London and New York: D. Appleton and Co. 1903. Pp. 696. Price 21s. net.

IT is an aphorism that the rapid reappearance of a medical work is some criterion of its merits and as the volume which we are now about to consider has entered upon its third edition within seven years from the appearance of the first a better index of its appreciation could hardly be desired.

To the first section, which treats of the Anatomy and Physiology of the Ear, there have been practically no additions made since the first edition. We, indeed, find no material alteration until the end of the first half of the book, in which some minor changes have been made in the discussion of the treatment of ceruminous impaction and the careful cleansing of the parts after rupture of the meatus—a proof of the careful way in which Professor Dench prepared his first volume for the press.

In the preliminary observations on diseases of the middle ear some very useful considerations are added, especially with regard to the precautions to be observed in detecting the various micro-organisms which are responsible for any particular case of inflammation in this part. And again, in acute catarrhal otitis media the advantage of this knowledge is shown in the influence which it has on the prognosis. In the treatment of acute purulent otitis media, when the mastoid is involved, we find that the practice of local abstraction of blood is still objected to by Professor Dench. As a means of dilating the Eustachian tube the electrolytic method is very carefully and fully described, though it is attributed to Dr. Duel in 1897, whereas it had been in use at least ten years previously, and probably before. Professor Dench also still holds the opinion that the injection of fluids into the Eustachian tube and tympanum is never wise but we may remark that this view is entirely at variance with the teaching of many European aural surgeons, of whom Politzer may be quoted as an example; in the next paragraph but one to that in which this opinion is expressed the injection of astringent solutions through the Eustachian tube after the membrana has been incised for the removal of fluid is given as an alternative treatment. We are glad to see that there is a paragraph under the heading of "Catarrhal Otitis Media" devoted to oto-sclerosis, the omission of which in the first edition is not easily explained, though the space devoted to this condition is neither in proportion to its importance nor to the size of the volume, and the same applies, but with greater force, to the brief remarks with reference to its diagnosis. Professor Dench is not at all an advocate of oto-massage, although he is still very much in favour of, and obtains extremely useful and beneficial results from, those operations devoted to the mobilisation of the stapes. The remark that secondary involvement of the mastoid process constitutes the most grave complication from which patients with purulent otitis media suffer might be altered with advantage in the next edition. It is in the description of the graver or intracranial complications following suppurative otitis media that Professor Dench has made the greatest improvements in the volume under consideration. Valuable additions have been made in the symptomatology and diagnosis both of meningitis and of sinus thrombosis, though in the latter instance the description is still a little meagre, while the subject of cerebellar abscess, which was omitted entirely from the first edition, now receives consideration. Some prominence is given to Ballance's method of skin grafting after operations on the mastoid and there are two new and excellent coloured plates showing the anatomy of the internal jugular vein, together with the areas exposed when searching for cerebral or cerebellar abscesses and in exploration of the lateral sinus. These are from dissections made by the author.

This volume, with the solitary exception of the rather scanty consideration given to otosclerosis, is of considerable excellence and maintains both the standard of thoroughness and the credit of being up to date established on its previous appearances. We are convinced that it deserves, and will amply repay, careful perusal.

Die Krankheiten der Oberen Luftwege. (Diseases of the Upper Air Passages.) By Professor MORITZ SCHMIDT. Third enlarged and improved edition, with 182 Illustrations and 7 Plates. Berlin: Julius Springer. 1903. Pp. 750. Price 18 marks.

THIS treatise on the Diseases of the Upper Air Passages covers a very large number of pathological conditions which, in the widest interpretation, cannot be said to be the particular property of the specialist; indeed, it has been Professor Schmidt's object to treat his subject not from the point of view of the specialist but from that of the general physician. In conformity with this method of treatment his book will doubtless be found to be of the greatest value to the practitioner who takes a wide view of his cases. That there are in Germany many readers to whom a book of this kind appeals is testified to by the fact that this is the third edition which Professor Schmidt has been called upon to publish. In his latest revision the author has introduced the recent and important work of Grabower and Edinger on the innervation of the larynx, tongue, and neighbouring structures. He has also introduced into his work some original schematic diagrams to illustrate the somewhat involved distribution of the hypoglossal, glosso-pharyngeal, pneumogastric, and sympathetic nerves which control the motor and sensory functions of the upper air passages. A careful study of the chapters which are devoted to general physiology and anatomy will enable the reader to appreciate the essential pathology and the rationale of the treatment of the diseases which the author describes in the sections which deal with special conditions. This general introductory portion we consider the most instructive part of the book. The general arrangement of the treatise is excellent but, as is so often the case with German works of this kind, the paragraphs are far too long and the illustrations for the most part are on a very meagre scale. A few of them, especially those which we have mentioned as appearing in the portion which describes the nervous distribution, are highly original and are first-class of their kind but for the rest they look as if they had been taken from the catalogues of instrument makers. As we have already mentioned, Professor Schmidt carefully avoids approaching the subject from what may be called a specialist's point of view. He lays the greatest stress on the influence of constitutional dyscrasiæ in the determination of local disease and the truth of this is at once manifest when we come to read that considerable portion of the book which is devoted to the inflammatory conditions of the upper air passages. For instance, in discussing the etiology of chronic laryngitis Professor Schmidt suggests that there is a strong family relationship between this condition and the early symptoms of glycosuria and of adiposis (*Fettleibigkeit*). And in accordance with this view of the pathology the author suggests a rational therapeusis which is little concerned with the local treatment which is so often applied in these cases. Hyperæmia and catarrh are in Professor Schmidt's opinion so closely associated that it is often impossible to differentiate where one begins and the other ends. He believes that the most common causes which produce both the one and the other are alcohol, hot and strongly spiced foods and drinks, and the ill-ventilated and heated conditions of sleeping and dwelling rooms. The best protection for the throat is never to wear a scarf round the neck; in fact, he is a strong advocate of the hardening system, cold air in the rooms, and exposure out of doors. In a work which is supposed to be confined to the diseases of the upper air passages it is natural to expect that considerable attention would be devoted to the exceedingly common condition of adenoids. It is therefore somewhat surprising to find that this subject is very cursorily dismissed In a very short account of the etiology the author considers that nervous disorders generally, and rickets in particular, are responsible for the development of these hypertrophic growths, and in this connexion we notice the somewhat curious statement that Barlow's disease, as an acute variety of rickets, may indirectly lead to the production of adenoids by interfering with the normal development of the jaws.

Although we consider that this book is invaluable for enlarging our views on the general pathological conditions which cause symptoms in the upper air passages we do not think that it will prove of much practical use to the specialist or to the practitioner who refers to it for information with regard to the specific treatment of disorders arising in these areas.

Atlas der Krankheiten der Nase, ihrer Nebenhohlen, und des Nasenrachenraumes (Atlas of Diseases of the Nose, its Accessory Cavities, and of the Naso-pharynx.) By Privatdocent Dr. P. H GERBER, Königsberg. Parts V., VI., and VII, pp. 28 Berlin: S. Karger. 1901. Price 6*s.* each part (separate parts not sold).

THE parts of Dr. Gerber's atlas under consideration contain 13 plates. The first (Plate XXII.) continues the series which deals with nasal suppuration and besides eight coloured figures there is a very characteristic lithograph of a man suffering from acute maxillary antrum disease in which the treatment adopted consisted of "hot compresses, cocainisation, rarefaction of the air, and iodide of potash." Plate XXIII. carries on the same series, dealing chiefly with ethmoidal and sphenoidal sinusitis. Plate XXIV. consists chiefly of black and white lithographs of cases of mucocele and empyema of the frontal sinus with dilatation taken chiefly from published cases by other observers. Plates XXV. and XXVI., also not coloured, are of simple and malignant nasal tumours. Plates XXVII. to XXX are of the varied forms of lupus and tuberculosis and are most beautifully executed and complete, Dr. Gerber having selected an excellent series of cases for the purpose of his Atlas Plates XXXI. to XXXV. are devoted to syphilis. Amongst the figures to which we would draw particular attention are those on Plate XXXI., which depict tertiary ulceration in the vault of the naso-pharynx. Plate XXXVI. shows forms of leprosy affecting the nose and palate and an example of malignant carbuncle of the nose. The coloured plates especially are all extremely well rendered; they leave nothing to be desired in their colouring and draughtsmanship and, as we have remarked before, the outline keys will render them of very considerable value to those who are not thoroughly familiar with the parts either when viewed directly through a speculum or when reflected in a mirror.

LIBRARY TABLE.

Army Inefficiency; its Greatest Cause. By A. C. PROFEIT, M B. Aberd. London: J. and A. Churchill. 1903. Pp. 57. Price 1*s.* net.—This is a pamphlet giving an account of the deplorable ravages caused by venereal diseases in the British army. It discloses a state of things calling for serious reflection. Its author, who writes after having had ample experience and opportunities of studying the subject, trusts that the facts being brought to the knowledge of the public may lead to some attempt being made to remove a set of conditions which he contends is not only a disgrace to the army but a menace to the empire. The matter is one to which attention has frequently been directed by ourselves and others and has again and again been made the subject of official and Government inquiry, but, we regret to say, with relatively little practical effect in the way of preventing or mitigating an evil the terrible nature and extent of which cannot be denied. It is confessedly a question of exceeding difficulty. Still, the author thinks that even were the limited means at our disposal thoroughly organised and every advantage taken of them much good might be done and he indicates various directions in which this should be attempted.

Cusack's Biology. Part I., Plant Life; Part II., Animal Life. By WILLIAM E. CLARKE. London: City of London Book Depôt. 1903. Pp. 268. Price 2*s.* 6*d.* net.—This book we learn from the preface has been specially written to fulfil the requirements of the biological syllabuses for the acting teachers and the King's scholarship examinations issued by the Board of Education. It will, we think, be found of great use, for it is very plainly written and does not assume, as do too many text-books, that the pupil knows something about the subject of his studies before he commences to learn. We may suggest, however, to the author that in Lesson xlvi. he should make it more clear that he does not mean that animals can live upon solid food unless it has been rendered soluble by means of digestion. In some of the drawings, too, it might be shown, for the benefit of those who do not know, which structures belong to the rabbit and which to the human being. But these are minor faults in a good book.

Transactions of the Society of Anæsthetists. Vol. VI. Session 1902–03. London: John Bale, Sons, and Danielsson. 1903. Pp. 86.—Several matters of great interest are included within the 86 pages of this modest volume of transactions. A case was reported by Dr. E. A. Starling in which arrest of respiration and of the heart's action occurred during the administration of ether. The heart was directly compressed through the diaphragm and eventually the patient recovered. At the third meeting of the society Mr. A. Vernon Harcourt gave an account of his apparatus for the administration of definite percentages of chloroform, and at the fourth meeting Mr. Foster Cross read a paper on Somnoform, a comparatively new anæsthetic.

Transactions of the American Pediatric Society. Fourteenth session. 1902.—This volume is a reprint from the *Archives of Pediatrics* and contains a number of interesting papers and discussions. The fourteenth session was held at Boston, from May 26th to 28th, 1902, and at its close a loving-cup was presented to Dr. T. M. Rotch. Among the papers included in eports we may mention one as being of interest to mothers as well as to physicians—namely, that by Dr. A. C. Cotton on the Effects of Tight Diapers. The paper is illustrated by diagrams which show well how an infant's thorax and pelvis can be compressed by a tight diaper.

Elementary Dispensing Practice for Students of Pharmacy and Medicine. By JOSEPH INCE, F.C.S. London: *The Chemist and Druggist.* 1903. Pp. 141. Price 3*s.* 6*d.* net.—This, it seems to us, is an admirable book. Unlike many written by those who know for those who do not know it is simple, clear except in one place, and does not assume knowledge where there is probably none. Now that so many medical men dispense their own medicines with their own hands (and we suppose that despite a recent proposal they will continue to do so) a book like this should find great favour with the country practitioner in remote districts, for it is full of useful hints. As an example of the clearness with which the book is written we may refer to the directions given on p. 88 for freeing the yelk of a raw egg from the white. There is nothing more easy to do when the doer knows how and nothing more difficult for him who has never done it before. There is surely a misprint on p. 113 where the following words occur: "Hydrarg. nitr. oxid.," or are they a contracted form of the obsolete name for the red oxide of mercury—namely, hydrargyri nitrico-oxidum? Anyway, the mystery should be cleared up in another edition. Mr. Ince, we learn from an editorial note, is nearing his eightieth year but we hope that while he is still with us he will write a simple cookery book on the lines of the work now before us, for it would be a boon to many a young housekeeper.

JOURNALS AND MAGAZINES.

School: a Monthly Record of Educational Thought and Progress. No. I., January, 1904 London: John Murray. Price 6*d.* net.—The sub-title of this new journal sufficiently describes its aims and objects and we can vouch that in this, the first number, they are excellently carried out. The Rev. T. L. Papillon contributes an article on Impressions and Results of the Mosely Commission wherein he praises American ideas as to education, the education itself being eminently practical and popular. Professor John Adams writes on the Training of Teachers and Sir John Lubbock gives an account of his early years which should interest all Etonians. Herbert Spencer is the subject of the leading article which points out how he insisted upon the fact that education is really self-instruction. The reviews, which are signed with initials, are particularly interesting and altogether the new magazine should prove a success. We are the more interested in it for by this first number it appears that its conductors have a true idea of what education really is—that is to say, not cramming knowledge into a child but the developing of what is already there in embryo. Only by acting on these lines can teachers hope for permanent success in their arduous and responsible office.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—Mr. Tree is organising a matinée which will be given on March 18th at His Majesty's Theatre for the benefit of the National Hospital for the Paralysed and Epileptic, Queen-square. The part of the programme already decided on includes the screen scene from *The School for Scandal*, *The Man Who Was*, *The Pantomime Rehearsal*, and Mr. Carton's duologue, *The Ninth Waltz*. The following actresses and actors have promised to appear: Mrs. Patrick Campbell, Miss Mary Moore, Miss Julia Neilson, Miss Violet Vanbrugh, Miss Irene Vanbrugh, Sir Charles Wyndham, Mr. Tree, Mr. George Alexander, Mr. Cyril Maude, Mr Fred. Terry, and Mr. D. G. Boucicault. It is believed that several other well known names will be announced later. Sir Lawrence Alma Tadema has promised to design a souvenir programme. Seats may be booked at the theatre.

Analytical Records

FROM

THE LANCET LABORATORY.

(1) "TABLOID" ZINC VALERIANATE; AND (2) "TABLOID" TRI-BROMIDE (EFFERVESCENT).

(BURROUGHS, WELLCOME, AND CO., SNOW HILL-BUILDINGS, LONDON, E.C.)

(1) THE sugar-coated tabloid of valerianate of zinc affords an excellent way of administering this unpleasant but useful drug. Each tabloid contains two grains of the valerianate and we found that the yield of zinc oxide on careful incineration corresponded with the amount of salt stated. The tabloids are quite free from smell or taste until the sugar coating is dissolved. The contents then break up readily in slightly acidified fluids. (2) The tabloid of tri-bromides contains approximately 15 grains of mixed bromides which are associated with an effervescent basis. We have confirmed the dosage of the respective bromides—namely, that of potassium six grains, that of sodium six grains, and that of ammonium three grains. As is well known, the administration of such a combination of bromides is in many cases more satisfactory than when an equivalent dose of a single salt is used.

"ALLENBURYS" MILK FOOD CHOCOLATE.

(ALLEN AND HANBURYS, LIMITED, BETHNAL GREEN, LONDON, E.)

This preparation is both confection and food and it is evidently made from well-chosen materials containing in addition 25 per cent. of the "Allenburys" Milk Food No. 1. Our analysis gave the following results: moisture, 0·95 per cent.; mineral matter, 1·62 per cent.; sugar, 56·41 per cent.; proteid, 7·62 per cent.; and fat, 33·40 per cent.

SPECIAL DIETETIC WINES.

(M. SCHREIBER, BADEN, NEAR VIENNA; AGENCY, C. H. BEAUMONT AND CO., 19, ST. DUNSTAN'S-HILL, LONDON, E.C.)

We have received two varieties of wine from the above firm. They are respectively "Special Marke Diätetischer Rothwein" and "Rauheneck" white wine. Both wines are the produce of Austrian vineyards and have been brought to our notice because they are said to present certain dietetic advantages. The Rauheneck, for example, "is the wine recommended during the cure in Carlsbad and Marienbad and is free from acid and consequently very suitable for the use of those suffering from gout and obesity, as solely used by his Majesty the King during his stay in Marienbad." Similarly the red wine (special mark) "is a natural wine, absolutely free from sugar (withdrawn by M. Schreiber's patent process), and is consequently safe as a beverage for diabetics." How far these claims are justified will be gathered from the following results of our analysis. Rauheneck wine (white): extractives, 1·55 per cent; mineral matter, 0·20 per cent.; alcohol, by weight 10·08 per cent., by volume 12·49 per cent., equal to proof spirit 21 89 per cent.; volatile acidity reckoned as acetic acid, 0·06 per cent.; fixed acidity reckoned as tartaric acid, 0·45 per cent.; and sugar, 0·14 per cent. It will be seen that this wine was in sound condition and practically free from volatile acidity and sugar. It is rarely that a white wine shows such an infinitesimal amount of sugar and acid as does this wine. The flavour is excellent and delicate. It should be added that the figure for sugar given above represents the reduction equivalent obtained with an alkaline copper solution. It is quite probable that the reduction effected is not due entirely to sugar. Diätetischer Rothwein (special mark), extractives, 2·11 per cent.; mineral matter, 0·25 per cent.; alcohol, by weight 10·85 per cent., by volume 13·43 per cent., equal to proof spirit 23·54 per cent.; volatile acidity reckoned as acetic acid, 0·09 per cent.; fixed acidity reckoned as tartaric acid, 0·18 per cent.; and sugar, 0·11 per cent. This is also a practically non-acid wine and free from sugar. It is a delicate red wine and pleasing to the palate. These results of analysis may therefore be said to confirm the claims made in favour of these wines for special dietetic purposes.

HERRINGS IN TOMATO SAUCE.

(J. M. DAVIDSON, GLASGOW, AND MOIR, WILSON, AND CO., ABERDEEN; AGENT, WILLIAM MACKINTOSH AULD, 151, HOLM-STREET, GLASGOW.)

On opening the tin containing this preparation the fishes were found to be whole and in perfectly sound condition. There was no sign of action upon the tin and an examination of the liquor gave negative results as regards the presence of injurious metal. The herrings used are small and are said to be taken from Loch Fyne. As is well known, the herring is excellent food and more particularly, perhaps, on account of the digestibility of the fatty portion. There is, however, no reason for believing that fishes of any kind are necessarily so-called "brain food," although the presence of glycero-phosphates in the form of lecithin, a substance which is known to improve the general nutrition of the nervous system, may be remarked.

STRECKEISEN'S FOODS.

(1) OAT MILK COCOA; AND (2) INFANTS' AND INVALIDS' FOOD.

(FRY AND CO., LIMITED, PENINSULAR HOUSE, MONUMENT-STREET, LONDON, E.C.)

The nutritive and general character of these foods may to some extent be estimated from the fact that the first is made with oats, milk, and cocoa, and the second with oats, milk, and flour. Both foods are carefully prepared and microscopic examination confirmed the description as to their general composition. The preparation of oat milk and cocoa gave the following results on analysis: moisture, 5·3 per cent.; mineral matter, 4·90 per cent.; proteid, 18·43 per cent.; fat, 18 00 per cent.; and starch, cellulose, &c., 53·37 per cent. The food is thus seen to be rich in nutritious elements. The preparation of oats, milk, and flour gave the following results on analysis: moisture, 3·10 per cent.; mineral matter, 2·00 per cent.; fat, 8·10 per cent.; proteid, 13 40 per cent.; and starch and cellulose, 73·40 per cent. This food is described as an infants' and invalids' food. According to this analysis it contains a higher proportion of carbohydrates than does the previous preparation and there is a corresponding reduction in the amount of both proteid and fat. The proportion of fat might from the point of view of the special requirements of infants be increased, judging at any rate from the amount of fat present in their natural food.

(1) RESORBIN; (2) PERUOL; AND (3) CHLOROFORM-ANSCHUTZ.

(CHARLES ZIMMERMANN AND CO., 9 AND 10, ST. MARY-AT-HILL, LONDON, E.C.)

These preparations are amongst the new pharmaceutical products of the Berlin Aniline Dye Co. (1) Resorbin is said to consist of an ointment vehicle "made by emulsifying almond oil and water by means of yellow wax and gelatin to which is added some lanolin." Its special feature is that it is readily absorbed by the skin and thus serves as an excellent vehicle for those drugs used in dermatological practice. Moreover, it is soothing and not at all irritating and contains a certain amount of water. Resorbin is combined with zinc oxide, mercury, and other drugs used in the treatment of diseases of the skin. Resorbin appears to form an excellent ointment basis for the metallic salts such as those of mercury and bismuth. (2) Peruol is a 25 per cent. solution in castor oil of benzoic acid benzyl-ester which is the active therapeutic salt of balsam of Peru. It is a colourless and odourless oil which is said to be employed with advantage in the same way as balsam of Peru in scabies and eczema. (3) Chloroform-anschutz is of decided interest, since it is prepared from a compound of chloroform with the anhydride of salicylic acid which is crystalline. The chloroform may be drawn off from these pure crystals in an absolutely chemically pure state. Anæsthesia is therefore induced by the chloroform so prepared with the risk of distress arising from the impurities of ordinary chloroform considerably diminished.

MONTI PIANO WINE.

(Morison, Pollexfen, and Blair, 34, Leadenhall-street, London, E.C.)

This is an excellent light, non-acid red wine from Castello, Italy. On analysis the following results were obtained: alcohol, by weight 8·64 per cent., by volume 10·73 per cent, equal to proof spirit 18·81 per cent.; extractives, 2·07 per cent.; mineral matter, 0·19 per cent.; fixed acidity reckoned as tartaric acid, 0·33 per cent.; volatile acidity reckoned as acetic acid, 0·072 per cent.; sugar, 0·116 per cent. According to these results, and they conform exactly to the impression recorded by the discriminating palate, the wine is of low alcoholic strength, contains practically no sugar, and is free from volatile acidity—in short, it is a genuine, pleasing wine.

NATURAL SODA-WATER.

(Cutlack and Co., Phœnix Brewery, Peterborough.)

The interesting feature of this water is that it contains naturally certain saline ingredients in important quantity, chief of which are the bicarbonate, chloride, and sulphate of sodium. The water is drawn from a well at the above brewery. According to our analysis the water yielded on evaporation 101·50 grains of mineral matter per gallon, consisting of carbonate of sodium, 40·06 grains (equal to 63·50 grains of bicarbonate); common salt, 45·04 grains; sulphate of sodium, 12·26 grains; and carbonates of magnesium and lime, 4·14 grains. There was no evidence of any organic impurity. The water contains ammonia in traces in the saline form. The taste is pleasant and "soft," which makes it admirably adapted for the purposes of an aerated water.

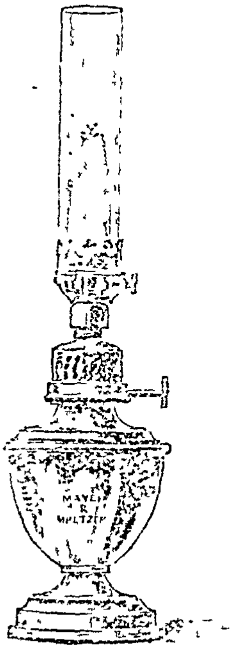
CIGARETTES OF SPECIAL MANUFACTURE.

(Louis Coen, 83, Piccadilly, London, W.)

There is no doubt that the tobacco leaf suffers considerable deterioration on its way from the plantation to the manufacturer. It easily absorbs foreign flavours and is also the subject of attack by moulds and insects, the ravages of which are calculated to impair the flavour of the tobacco when smoked in the pipe, cigarette, or cigar. This impairment is claimed to be rectified by a process introduced by the above manufacturer. Instead of using ordinary water for damping the leaves in order to prepare them in a convenient state for cutting he sprays over the dry leaf certain natural mineral waters which he asserts have a freshening or ozonising effect upon the tobacco. However that may be, the result is certainly very satisfactory from the smoker's point of view. There is a sweetness about the flavour and fragrance of the smoke which recalls that of very choice tobacco which has been most carefully handled. It is well known that the aroma and fragrance of tobacco smoke develop considerably in fresh air or in contact with ozone. This ozonising process, as the inventor claims it to be, would appear to have a similar effect. The flavour of both Dubec and Virginia tobacco is considerably improved. It is also claimed that this treatment destroys grubs or insects in the leaf by virtue of the insecticidal action of the oxygen contained in the water employed in the way described. Of course, mineral salts would have a tendency to neutralise any acids that may be present in the tobacco, although according to our analysis the process adds very little to the mineral contents of the tobacco, while its combustibility is certainly not interfered with. It is not pretended that the process makes bad tobacco good but that it removes unpleasant adventitious flavours when they are present.

New Inventions.

A PORTABLE LAMP FOR LARYNGOSCOPIC PURPOSES.



The lamp shown in the accompanying figure has proved itself very useful to me for carrying to patients' houses. It is an incandescent lamp burning methylated spirit and in case of injury to the mantle a spare one is carried in the box, also a small reserve of spirit. The whole fits into a wooden box measuring 13 × 5½ × 8½ inches and it is not at all heavy. With ordinary care there is no risk of the spirit contained in the lamp spilling. The lamp gives out a bright white light and is useful not only for examination of the throat, the nose, and the ear, but for other surgical work. The want which exists for a portable, and at the same time powerful, light is my excuse for drawing attention to this simple lamp. It is moderate in price and may be obtained of M. Vaast, 22, Rue de l'Odéon, Paris, or of Messrs Mayor and Meltzer, 71, Great Portland-street, London, W.

E. Cresswell Baber.

Brighton.

A NEW INCH MEASURE.

We have received from Mr. F. W. White of 26, Browning-road, Manor Park, Essex, a simple, ingenious, and novel inch measure which Mr. White calls the "inch wheel." It is a six-pointed star made of aluminium and the distance between the points of any two adjacent spurs is exactly one inch, so that each revolution measures six inches. In the centre of the star is an eyelet around which the star revolves On using the measure the eyelet is held between the forefinger and the thumb and the star is run along paper and similar substances like a wheel. The points of the spurs will upon slight pressure leave a dent on paper and similar substances when being measured. By marking these dents a piece of paper or a lath of wood can be readily transformed into a measure of any length. The inventor says that slippery surfaces, such as glass, marble, and the like, can be measured easily by placing a sheet of paper over them first. The "wheel" is especially useful in map measuring where it is necessary to follow the course of a winding road. It would also, we think, prove of service to the surgeon who needs to measure the length or circumference of a limb, say, for a splint. The points cause no pain when the measure is applied to the skin. Of course, there is a slight inaccuracy in measuring curved surfaces, for the measure gives us the lengths of a number of chords instead of the arcs which they subtend, but the difference would be slight and hardly of practical importance. We might suggest that a similar star measuring centimetres might also be of value. The price of the inch wheel in a neat pocket case is 3*d*., or 4*d*., post free, from the inventor and patentee.

Royal Botanic Society of London.—A Horticultural and Gardening Exhibition will take place in the month of June this year under the auspices of this society. The exhibition will be held in the new exhibition grounds of the society situated in the centre of its beautiful gardens in Regent's Park and will be open for one week or possibly longer. The proposed scheme embraces horticulture, forestry, botany, educational methods, nature study, and a special section for colonial produce. In addition to the exhibition, lectures, conferences, and conversazioni are in course of arrangement. All communications respecting the exhibition should be made to Mr. J. Bryant Sowerby, the secretary.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 6, 1904.

Medical Examinations for Life Assurance.

THE medical examination of individuals applying for life assurance presents many problems of interest and the medical advisers of life assurance societies work under conditions different from those which are the rule in dealing with patients. Instead of having to meet the frail and the abnormal their interviews in the majority of instances are with the sound and the robust. Occasionally cases of latent disease are encountered, more particularly phenomena associated with arterio-sclerosis and glycosuria. The powers of observation and the ability for estimating differences in temperament are taxed to the uttermost, the great element of success in this branch of medical practice being the capacity to make correct forecasts and a sound prognosis. A thorough knowledge not only of his profession but of human nature and mankind in general is therefore a most valuable qualification for a medical examiner for life assurance. Until a comparatively recent period there has been no organised endeavour to utilise the wealth of experience gradually accumulated by medical practitioners who have especially studied the medical side of life assurance. Fortunately, however, this defect no longer exists, for the Life Assurance Medical Officers' Association now provides opportunities of collating and discussing the many questions constantly presenting themselves in this branch of professional duty. Sir DYCE DUCKWORTH in delivering the presidential address before that society on Jan. 27th, a report of which will be found in another column, referred to the valuable work which the association has already accomplished and which has fully justified the expectations of its originators. He pointed out that some of the most profitable discussions that have taken place related to the subjects of albuminuria and glycosuria and much information has been elicited which has enabled the members to gauge the significance of such symptoms in a more precise manner than had previously been the case. He also touched upon other subjects of medical interest in connexion with life assurance.

One of these seems to us to deserve very careful consideration—namely, the practice recently adopted by certain societies of accepting applicants for assurance without medical examination. From a professional point of view there can scarcely be two opinions on this point. Dr. E. SYMES-THOMPSON writing in Professor CLIFFORD ALLBUTT'S "System of Medicine" (vol. i., p. 476) states that the medical selection of lives was not attempted in the early days of life assurance. The first society, the Amicable, was founded in 1706 and existed for some years before a medical officer was appointed. The same premium was paid by each applicant, whatever his age or apparent health. He was, however, called upon to state on oath that he believed himself to be a "good life." In process of time it was found desirable to exclude manifestly unhealthy applicants; hence the proposer was required to appear before the board. Some directors were shrewd in their judgment as to the value of a life but it soon became apparent that a medical inspection was required for the selection of "first-class" lives. According to Dr. SYMES-THOMPSON the first medical officer was appointed to the "Amicable" in 1855 and to the "Equitable" in 1858, but we believe that other offices had made similar appointments previously to that date. We have before us the proposal form of one of the societies which adopt the system of dispensing with the medical examination of applicants for policies. The sum assured must be £500 and upwards. The questions do not materially differ from those asked by other companies except that descriptions of previous illnesses and the details of the family history have to be given by the proposer instead of by the medical examiner. The disadvantages of this procedure are obvious. The applicant has then to sign a declaration to the effect that the statements in the proposal form are true and correct and that if any untrue averment is contained in the said statement, or if it is afterwards shown that any material information has been withheld, then the contract shall be void and all moneys which shall have been paid on account of the assurance shall be absolutely forfeited to the society. As Sir DYCE DUCKWORTH said, this practice is both precarious and troublesome and is certainly designed to attract persons who have no just claim to exemption from the ordinary and proper examination. If an individual is aware that he has some organic defect which may render him ineligible for assurance at ordinary rates in other societies it is a great temptation to him to go to a society which offers him assurance without medical examination. He will then, of course, find it impossible to avoid making false statements in filling up his proposal form and if it is afterwards discovered that he has knowingly committed a fraud he meets with just punishment in having the contract annulled with the loss of the premiums which he has already paid. Instead of running this risk it would have been wiser of him to have applied for a policy as a sub-standard life and to have submitted to a medical examination, for many assurance companies now accept such lives under certain conditions Another excuse for wishing to escape a medical examination is the trifling loss of time which is entailed by a visit to the medical examiner. We cannot, however, consider it as time misspent, for it insures a policy granted in circumstances which in certain offices render it practically unassailable. There is a further objection and a very strong one to assuring without medical examination—namely, that if the applicant should die from disease during the first year following the date of assurance the amount payable is only one-third of the sum assured, if he should die during the second year two-thirds of the sum, but on a claim occurring at any time after two years from the date of assurance the full sum assured is payable. If death is due to accident of course no deduction is made. In the case of assurance with medical examination if death takes place at any time after the policy is issued the claim is paid in full. We cannot understand therefore where the advantage to the general public, whether as holders of assurance policies or as eventual beneficiaries, is to be found under the conditions of the practice which we are *discussing*.

With regard to the society itself, also, it is difficult to see where the benefit can lie. Doubtless a large number of applications might be received but the risk of fraud and deceit must be constant and if many claims are contested this method of insurance would quickly become unpopular. Sir DYCE DUCKWORTH suggested that the practice had its origin in the same causes which so gravely affect the conduct of all business transactions in these days—namely, hurry, pressure, and furious competition. The business aspect of this question has little concern for us as members of the medical profession but we shall watch with interest the results of a step which we can only consider as retrograde.

◆

"Eye-strain."

OUR esteemed colleague Dr. G. M. GOULD of Philadelphia, editor of *American Medicine*, in further pursuit of his strenuous endeavours to arouse the medical profession to a complete consciousness of the frequency, the nature, and the consequences of "eye strain," has sent us a paper upon the subject which is appearing in the current number of that journal. In this he repeats many of the assertions with which his former writings have rendered us more or less familiar, although they have not as yet come to command the entire assent of which their writer no doubt believes them to be worthy. Dr. GOULD tells us that a large number of cases of neurotic character, defects of temper, defects of digestion, incapacity for sustained work at near objects, migraine, and a large catalogue of the peculiarities which have been sometimes described as the defects of genius, are mainly due to unrecognised "eye-strain" produced by astigmatism, generally of the hypermetropic character, and he gives us quite a long catalogue of illustrious sufferers, including people of characters so diverse as the CARLYLES, GEORGE ELIOT, HUXLLY, DARWIN, and NIETZSCHE Our readers will remember that Dr. GOULD contributed a lengthy article to our columns last autumn,[1] in which he endeavoured to prove by extracts from the life of WAGNER, and by photographs *showing an outward deviation* of his left eye, that he also should be added to the long list of illustrious sufferers from eye-strain, and he dwelt upon the assertion that the pains and troubles of genius, with which all the world becomes familiar, are daily passing unrecognised among thousands of the obscure. Not very felicitously, perhaps, he assures his readers that the evil to which he desires to call attention is rampant and unchecked, that "*the vast majority of so-called refractions is worthless*," and that in Europe "all refraction (? refraction testing) may be said to be unscientific, inaccurate, and without power to cure the symptoms and sequels of eye-strain." In the opinion of our friendly monitor Europe is clearly called upon to take a back seat.

We have been at *some pains to ascertain the views* of London ophthalmologists upon the questions to which Dr. GOULD directs attention. It must be remembered that "eye-strain" or, as he called it, weak sight or asthenopia, was quite clearly known to, and described by, MACKENZIE in 1830, but that he knew it only as an ultimate fact, had no conception of its nature, and had no other treatment than the abandonment of near work to suggest. Its cause was first made known when DONDERS discovered the existence and the frequency of hypermetropia, and was still further elucidated by his subsequent discovery of the frequency of astigmatism—a condition which, although it had been discovered by YOUNG and again by AIRY, in their own persons, had not been generally recognised by surgeons. A few years were required before the fruits of these discoveries were at all generally realised; but the possibility of curing asthenopia by spectacles was fully present to the minds of English ophthalmologists in the early "sixties," and the careful use of spectacles for visual discomfort has never since been neglected in this country. Some of the examples of real or supposed eye-strain selected by Dr. GOULD had endured their fate, whatever it might be, before the time for scientifically selected spectacles had arrived; and it is now but a vain speculation to consider whether he may have lighted upon a correct interpretation of their symptoms. At the present day, unquestionably, both physicians and the public are fully aware of the occasional, or even frequent, dependence of various forms of headache upon errors of refraction; and there is no ophthalmologist who is not constantly consulted upon the questions hence arising both in children and in adults, sometimes spontaneously by the patient, more frequently at the suggestion of physicians or teachers. So much is this the case that the ophthalmic consultant is often compelled to give the eyes a clean bill of health, and to say that the causes of the trouble must be sought elsewhere. Nor is it found, generally speaking, that the symptoms attendant upon proved astigmatism are so serious as Dr. GOULD would have us believe. DONDERS was probably not far wrong when, after pointing out the almost universality of the condition, he said that a degree of less than a dioptre was rarely disturbing to vision. Nothing is more common in presbyopic hypermetropes than to see astigmatism first become manifest at the age of 40 years or thereabouts, and then to call for correction *not so much* for the relief of discomfort as for the improvement of sight. In *London* consulting rooms and hospitals, at least, refraction is tested with a degree of care and accuracy which could *not* be surpassed, either in Philadelphia or anywhere else, and we are quite unable to accept Dr. GOULD'S opinion to the contrary. We recognise that he has done good work in calling the attention of the profession in America to conditions which there may possibly be as much neglected as he believes them to be; and we cordially endorse his opinion that the eyes should be examined by an expert in every case of migraine. In London this condition is generally fulfilled; and, if Dr. GOULD'S opinions be correct, it is certain that our future CARLYLES and DARWINS *and ELIOTS will* be able *to pursue their* work in life without hindrance from the painful difficulties which he describes.

---

[1] THE LANCET, August 1st, 1903, p. 306.

The Revaccination Bill, 1904.

WE publish in another column the text of the Revaccination Bill, 1904, the title of which is "An Act to Provide for the Revaccination of Children after the age of 12." The names on the back of the Bill are those of Sir MICHAEL FOSTER, the Right Hon. R. B HALDANE, Dr. FARQUHARSON, Captain JESSEL, Mr. HEYWOOD JOHNSTONE, Sir JOHN BATTY TUKE, Sir CHARLES DALRYMPLE, Mr. IAN MALCOLM, Sir JOHN DORINGTON, Sir ANDREW AGNEW, Sir RICHARD JEBB, Mr. T. P. O'CONNOR, Dr. E. C. THOMPSON, and Mr. B. L. COHEN. The result of the ballot for the reading of new Bills will not be known until next week, so that it is impossible at the present moment to predict the chances that the Bill has of becoming law. The wording of the Bill is so plain that no exposition of the various clauses is required. If it becomes law it will make the revaccination of children at the age of 12 years compulsory. The provisions of the existing Vaccination Acts, as they relate to the appointments, duties, and remuneration of public vaccinators and vaccination officers, are to be construed as applying to the new legislation, while nothing in the new Bill, if it should become law, is to be taken to repeal or to modify any of the provisions of existing vaccination legislation. In the Revaccination Bill the conscientious objector is to be relieved of the penalties incurred by infringing the Vaccination Act of 1867 upon lines similar to those laid down in the "conscience clause" of the Vaccination Act of 1898. Within four months from the time of his child attaining the age of 12 years the parent or guardian has to satisfy two justices in petty session that he conscientiously believes that revaccination would be prejudicial to the health of the child. Within seven days from making this statement he is to deliver to the vaccination officer for the district a certificate by such justices of his conscientious objection, when he will be free from penalties. It is not proposed to include Scotland and Ireland in the working of the Bill.

All medical men will join with us in hoping that so reasonable a piece of legislation will obtain the support of the House, and if those in charge of the Bill secure a good place in the ballot there seems to us no reason why a very valuable and necessary addition to the statute book should not immediately take place. The Government, as is well known, is virtually pledged to bring in a measure of revaccination. It is true that since those pledges were given much has happened to the Government. It is no longer relying on the strong and coherent support of a large majority; upon the fiscal question the party appears to be divided quite sharply and on other matters, of great if not of such extreme import, differences of opinion exist between Members sitting on the same benches. But the party position of Mr. BALFOUR'S administration ought to make no difference to the fortunes of the Revaccination Bill. Upon such a question as revaccination there is no need for acrimonious discussion. Scientific opinion is unanimously in favour of such a measure, and the proofs in support of the benefit to the nation of revaccination are enormous. Time after time experience has shown that the revaccination of children confers practically complete immunity against epidemic small-pox. The Bill is a necessary complement to our existing vaccination legislation. Whatever be the fault of the "conscience clause" of the Act of 1898—and experience of the working of the clause cannot have made thoughtful people very enthusiastic about it—it at least had the advantage that it opened wide the door for the measure which we hope may become law this session. No "conscience clause" should ever have been proposed and passed without the accompaniment of a revaccination clause, and Lord LISTER'S support of the last measure—a support which won the approval of a House of Lords which had previously shown a hostile face—was only given on the distinct understanding that legislation for revaccination would be considered by the Government in the recess and introduced when Parliament next met. That happened four years ago and the country still waits. The Government should, we think, seize the first opportunity of redeeming its promise, while opponents to the Government can surely see nothing in the Bill to oppose.

Annotations.

"Ne quid nimis."

STREET AMBULANCES FOR LONDON.

WE have on various previous occasions commented upon the crying need which exists in this overgrown city of London for an efficient system of ambulances for the conveyance of those injured in the streets to a hospital or to their own homes Letters have recently appeared in the *Times* calling attention to the matter, so that it will be particularly opportune to remind our readers of the work of the Metropolitan Street Ambulance Association. This association has recently been formed, with Mr. Reginald Harrison as president and Dr. Arthur W. James as secretary, and members of the medical profession are invited to join it. Dr. James, in a letter to us, mentions that there is no subscription as sufficient funds are in hand. The association is composed entirely of medical men, presumably London medical men, and all members are asked to work during the coming London County Council elections to impress upon candidates the need for forwarding the adoption of an efficient system of street ambulances for London. At present the only horsed ambulances in London are those provided by the St. John Ambulance Association, one or two belonging to certain hospitals, and those provided by the Metropolitan Asylums Board. Hand ambulances and stretchers are placed in a few streets and they are procurable for use by a series of processes which remind us of the finding of the giant's heart in the familiar fairy tale. The person in need has to break a glass and to take out a key, with the key to unlock a cupboard, in the cupboard is a box, and in the box is a stretcher; but it must be allowed that some such machinery is required in the absence of proper ambulance stations. The London County Council has been considering a scheme for street ambulances for some time, but nothing has yet been done and at present the citizen who falls or injures himself in the street is in far worse case than an omnibus horse, for the two great omnibus companies keep ambulances for the use of their injured equine servants, although none, we think, for either drivers or conductors. We recommend our readers to communicate with Dr. James, 69, Gloucester-terrace, Hyde-park, W., to join the Metropolitan Street Ambulance Association, and to worry their representatives upon the London County Council in accordance with the objects of that association.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

Dr. Horace Dobell of Parkstone Heights, Dorset, formerly of Harley-street, London, has presented £500 in Consols (cumulative) to the Royal College of Physicians of London, for the promotion of original research into the ultimate origin, evolution, and life-history of bacilli and other pathogenic micro-organisms. The conditions are that the President and Censors of the College shall select a lecturer once in every two years who shall give a lecture recording original researches on the above subject made by himself and others and that he shall receive a fee of £50 for so doing. These lectures are to be continued biennially so long as a sufficient amount of the £500 and its accumulated interest remains. The first lecture will be delivered in November, 1904, by Dr. E. Klein. The Milroy lecturer for 1905 is Dr. Thomas Morison Legge, one of His Majesty's inspectors of factories, who has taken as his subject Industrial Anthrax.

THE ADULTERATION OF COD-LIVER OIL.

WE are indebted to Mr. E. J. Parry, B.Sc., F.I.C., for a communication in which he states that the great scarcity of cod-liver oil during the past year or so, accompanied by famine prices on the market, has been responsible for an enormous amount of adulteration in this product. Various adulterants have from time to time been recorded but at the present time "low-grade" fish oils other than the genuine cod-liver oil are almost universally found in adulterated samples. There is at present, Mr. Parry states, and he is a well-known authority on the subject, a very brisk demand for empty cod-liver oil barrels and he has been able to trace enormous numbers in one place. The original marks are obliterated and the barrels are re-painted and re-marked and eventually three barrels of genuine cod-liver oil re-appear on the market as five and the stock of shark oil is correspondingly diminished. Such transactions he has been able to trace from beginning to end. As regards examination a trained nose is of considerable help. The tests given by the British Pharmacopœia are practically useless except in so far as they bring the adulterants within a certain group on account of a specific gravity limit and they exclude oils which freeze at 32° F. in two hours. Again, the specific gravity, the saponification value, and the iodine absorption figure give no useful indications except when taken in conjunction with other figures. The amount of free acid present in the samples, the index of refraction, and certain colour reactions do give in some cases most valuable information. Mr. Parry has found that of the 58 samples examined by him during the past year 21 proved to be pure, nine doubtful, and 28 were clearly adulterated. Altogether the results show that there is an enormous amount of adulterated cod-liver oil on the market and Mr. Parry's experience is in complete agreement with that of other analysts. A large proportion of this adulterated oil is undoubtedly used in preparations of cod-liver oil, such as cod-liver oil and malt extract and emulsions. The percentage of cod-liver oil in such preparations has been found to be as low as from 7 to 9. Mr. Parry suggests that this adulteration of cod-liver oil gives an admirable opening to physicians to consider, in view of the difficulty of depending on the supplies of cod-liver oil, whether its virtue as a medicine is really existent in any special sense, or whether it is more or less traditional and therefore much exaggerated, or, in other words, whether it is not as a fat of animal origin that cod-liver oil enjoys a reputation which it ought to share with other animal fats. It is open to question, we think, whether cod-liver oil has any specific virtues other than those of an easily digested fat. All the same, we trust that our authorities who are responsible for the practical application of the Sale of Food and Drugs Act will make a prompt inquiry into this matter and take steps to stamp out yet another barefaced imposition.

THE TEACHING OF HYGIENE IN SCHOOLS.

A CIRCULAR letter signed by most of the leaders of the medical profession in Great Britain and Ireland has been issued to the medical practitioners of these islands inclosing a petition for signature. The petition is to the central education authorities of the United Kingdom and asks them "to consider whether it would not be possible to include in the curricula of the public elementary schools and to encourage in the secondary schools such teaching as may, without developing any tendency to dwell on what is unwholesome, lead all the children to appreciate at their true value healthful bodily conditions as regards cleanliness, pure air, food, drink, &c." The petition goes on to state that in the opinion of the petitioners the most prominent subject is "the question of the nature and effects of alcohol." We are quite at one with the signatories of the circular as to the necessity for teaching children these matters, for the children of the present day will be the fathers and the mothers of the next generation, and it is well to make a beginning, but the task at present seems rather hopeless. Those classes of society which at the present time are most injuriously affected by unhealthy conditions are the very classes which are most prolific. They live in the most unhygienic circumstances, they sleep seven or eight of all ages and sexes in one small room, and as for alcohol, who can wonder that they try to drown sorrow for at least a few hours in the temporary euphoria which gin produces? We wish all success to the petition and hope that the educational authorities will take favourable notice of it. But we must own that we are not sanguine of any good results at least in the lifetime of this generation.

THE METROPOLITAN ASYLUMS BOARD AND ITS ASSISTANT MEDICAL OFFICERS.

WE commented in our issue of Jan. 16th, p. 175, upon the abrupt dismissal by the Metropolitan Asylums Board of certain of its assistant medical officers. That the Board in its action has in the main been actuated by motives of economy we do not doubt, but even if these motives were reasonable and pure—and we are not certain that this is the case—they would be inadequate. The assistant medical officers were invited to serve the Board when the Board was in sore need and should not have been dismissed without proper consideration unless the expense of retaining them bore some impossible relation to general expenditure, while their inutility was also not to be denied. The Board ought to be in a position, before taking drastic and ungracious action, to show that it has at the present moment a plethora of medical officers, a thing which does not seem at all clear to those who know the public health of London. It should also be able to foretell that it will not in the near future require again emergency assistants and there is no reason to regard the members of the Board as sound prophets in the least. A complication has now arisen in that certain of the assistant medical officers who have been dismissed with grave want of courtesy at a month's notice are actually in possession of agreements which may make the action of the Board illegal. Certain of the dismissed officers have taken legal advice on their position under their contracts with the Board, with the result that they are, we believe, prepared to test the course pursued by the Board in a court of law. If they are driven to this extremity they will be right to exact from the Board everything to which they are legally entitled for wrongful dismissal and for public discredit, while the public will turn an observant eye on the manner in which the affairs of the Metropolitan Asylums Board are managed. We all know of the grave waste of money that has taken place in certain of the building operations of the Board and can quite understand that economy is a necessity, but we do not appreciate in what way the cause of economy will be served by under-staffing the hospitals of the Board or by attempting to obtain the unpaid assistance of young gentlemen who cannot have had any opportunities of learning their duties. The economy of the Board will appear very doubtful when, as may be likely if the present course is persisted in, it is again compelled to invite the assistance of the medical profession, only to find that no one cares to go to the aid, at any rate without very high pay, of a body the gratitude of which is so fleeting. The Board will presumably take legal advice about the claims of those of its assistant medical officers who know that they have been treated illegally as well as meanly. Even if the Board should be recommended by its lawyers to contest the claims we hold that it would be wiser to reinstate the dismissed officers. For otherwise we foresee that the Board will find it very difficult to obtain medical service.

THE SURGERY OF CEREBRAL TUMOURS.

The reaction which followed the indiscriminate resort to operation for cerebral tumours 15 years ago which was stimulated by the publication of the successful cases of Horsley and Godlee, has led to an ultra-conservative attitude towards operation by many neurological surgeons and physicians. The proportion of cases of cerebral tumour suitable for radical surgical treatment has been estimated by various writers at from 2 to 12 per cent. According to Allen Starr about 7 per cent. of all cases of cerebral tumour are operable. With improvements in the methods of cerebral localisation and of technique during recent years operation has become safer and the proportion of operable cases has increased to a slight extent. In the *American Journal of the Medical Sciences* for December, 1903, Dr. George Woolsey of New York gives an account of the lessons to be drawn from the recorded cases of cerebral tumours (including five cases personally observed) operated on and reported during the past five years—a total of 101 cases—with a view to determine whether the results do not justify a less conservative attitude towards their operative treatment. The cases reported in the five years (since 1898) indicate, adds Dr. Woolsey, "that a more hopeful view may be taken of the surgery of cerebral tumours." In the series of 101 collected cases 12 showed the presence of cerebral tumours in the frontal region, including the so-called motor area. In eight of these the tumours were in the prefrontal lobe and presented the characteristic group of physical and mental symptoms, of which a special account was given in The Lancet[1] some years ago. Since then Schuster has published an analysis of 775 cases of tumour of the brain accompanied by psychic disturbances and has shown that tumours of the pre-frontal lobe produce dementia and moral deterioration more often than tumours elsewhere in the cerebrum Gianelli and von Bruns have also referred to the special mental disturbance accompanying such lesions of the brain. All of the eight cases of tumour limited to the prefrontal lobe only, which were collected by Dr. Woolsey, showed, irrespectively of the side involved, symptoms of mental disorder and moral perversion. In the parietal region five cases of tumour were recorded. All these presented definite localising symptoms and in four of them these symptoms included astereognosis. Three cases of tumour occurred in the occipital lobe of the brain. In all three there was homonymous hemianopsia which, says von Bruns, alone or associated with signs of visual irritation or hallucinations or of word-blindness is characteristic of tumour of the occipital lobe. This is confirmed by the cases collected by Dr. Woolsey who sums up his conclusion in terms to the effect that tumours in the prefrontal, parietal, and occipital areas are as localisable and operable as tumours of the Rolandic or "motor" area, and that the results of operation in the former have been quite as good as in the latter. The number also of operations on tumours in regions other than the motor area has largely increased in the last five years and the results justify the extension of surgical operation to regions outside the motor area. Summarising the diagnostic features of cerebral tumours Dr. Woolsey states that persistent headache is the most constant symptom and that it occurred in 90 per cent. of the collected cases. Early optic neuritis ("choked disc") was mentioned as present in 84 per cent. Vomiting and vertigo were present respectively in 33 per cent. and 22 per cent. of the cases. In addition to these general symptoms and to the special localising symptoms—local paralysis and tenderness to local pressure on the scalp—the importance of the x rays in diagnosis is insisted on. In many cases the results have been positive and justify the use of this method. The indications for operation are imperative, says Dr. Woolsey, when the tumour can be satisfactorily located in a region accessible to surgical operation and when there is no evidence that the growth is multiple or malignant in nature. The weight of evidence was also in favour of operation upon gummata of the brain, since antisyphilitic treatment might temporarily improve the symptoms but rarely, if ever, caused the entire absorption of the gumma. When severe headache and rapid loss of vision were noted, but localising symptoms were absent, trephining was advised as a palliative measure to give relief, which was often considerable, to the patient. But the temptation to make exploratory incisions or punctures in search of the tumour should, says Dr. Woolsey, be resisted. As regards prognosis the mortality in all cases operated on for cerebral tumour, according to the statistics of Chipault and of Allen Starr, was about 56 per cent. Selecting the cases in his records where an exact localisation was made Dr. Woolsey finds that the mortality was 22 7 per cent, as against 46 per cent. among the cases not exactly localised. In palliative operations and where the tumour cannot be found it is advised that the bone should be removed from the flap to relieve intracranial pressure and that a thin plate of celluloid should be introduced to prevent union of the scalp with the dura mater. The results varied, concludes Dr. Woolsey, from a nearly complete cure to the relief of the distressing pressure symptoms but in 6 per cent. of the cases no improvement followed.

ARSENIC IN BEER: ACTION FOR DAMAGES.

In the action brought by Messrs. Bostock and Co. of Liverpool (the firm who supplied sugar contaminated with arsenic to brewers for making beer which caused an epidemic of arsenical poisoning) against Messrs. John Nicholson and Sons of Leeds to recover damages for supplying sulphuric acid containing arsenic judgment was given in favour of the plaintiffs, but the questions of damages and as to how judgment should be entered were deferred. The case presents, of course, many points of interest in connexion with the supply of uncontaminated food which it will be proper for us to discuss at a future time. The award not having been given it is not possible to say to what in effect the judgment amounts. Mr. Justice Bruce decided that there was a contract for the sale of "B.O.V." which meant between the plaintiffs and the defendants an acid free from arsenic, so that when "B.O.V." was delivered in March, 1900, containing arsenic there was a breach of the implied condition. He further expressed the opinion, however, that the plaintiffs' chemists ought, as part of their duties, to have discovered arsenic in both the acid and the sugar, while the change in the colour of the acid supplied in March, 1900, which led to the mischief, ought to have aroused suspicion. The consideration of these facts will no doubt affect his lordship's decision as to the damages awarded, the amount claimed being £300,000.

STREET NOISES.

AT length the legal worm has turned and in saying this we hope that Mr. Sheil and Police-Constable 208 B will forgive us. On Jan. 30th four able-bodied labourers appeared before Mr. Sheil charged by the constable in question with placing themselves in a public thoroughfare for the purpose of gathering alms. They had a barrel organ on which was suspended a card with the words "Out of work" inscribed thereon. The constable took them into custody and Mr. Sheil gave to each of them one month's hard labour. He added that if they came before him again they would have three months. We do not in the least cavil at the sentence but we wish that the magistrate had made it more clear for what offence the men were sentenced. Organs, both piano and barrel, are only too common and, as one of the prisoners pertinently remarked on being taken into custody, "Why shouldn't we play an organ as well as the Italians?" We confess that we can only repeat the question. If four men can be arrested for going about with an organ bearing a placard to solicit alms why should not the Italian or Briton who does the same minus the placard be also arrested and get a month's imprisonment? Yet time after time magistrates have told us that the aggrieved brain-worker cannot order an organ away unless he has sickness in his house or is prepared to give some other reason than that he simply does not want the organ to play. All persons who play organs in the streets "place themselves in a public thoroughfare for the purpose of gathering alms," and we are quite willing to allow that in some places they are welcome. But in the Strand, for instance, no one wants them and in the quieter residential districts it will be a boon to the householder if he can ask a constable to arrest incontinently the player of a piano organ if he refuses to go away. Then London will be a somewhat less wearisome place to live in than it is at present. But we must confess that Mr. Sheil's action puzzles us.

NEURO-FIBROMATOUS TUMOURS OF THE BRAIN.

Professor Joseph Fraenkel and Dr. J. Ramsay Hunt of New York contribute to the *Medical Record* of Dec. 26th, 1903, an account of an interesting group of cases of cerebral tumour characterised by the development of neuro-fibromata on the cranial nerves situated in the ponto-bulbar region within the posterior fossa of the skull. The occurrence of such tumours is uncommon and they have hitherto been regarded as beyond the reach of surgical operation. It is only recently that precise knowledge has been obtained of these growths. Thus in 1902 von Monakow reported three cases in which the anatomical and clinical features were accurately stated and called attention to the possibility of surgical operation. Professor Fraenkel and Dr. Hunt record five cases with necropsies of such neuro-fibromata. Three of these affected the auditory nerve on one side, one affected the trigeminal nerve, and the fifth involved both auditory nerves. The tumours were encapsuled and varied in size from that of a cherry to that of a hen's egg. They caused atrophy of the nerves involved. Sternberg believed that these tumours arose from embryonic "rests" of the dorsal cranial nerves—viz., the trigeminal, acoustico-facial, and vago glossopharyngeal—all of which arise in the embryo from the dorsal lip of the neural ridge of epiblast. Early focal symptoms referable to a single cranial nerve appear during the growth of such tumours, the symptoms being slight in intensity and long in duration owing to the benign nature of the growth. They include tinnitus aurium, progressive diminution of hearing, attacks of labyrinthine vertigo, and occasional attacks of facial neuralgia As the growth increases symptoms of pressure on the neighbouring parts are manifested, such as ataxia of the cerebellar or peduncular type, nystagmus, irregularities of size and reaction of the pupils, ophthalmoplegia externa, dysarthria, dysphagia, facial paralysis, and disturbances of cardiac and respiratory functions. The diagnosis depends on the presence of the above symptoms combined with headache and optic neuritis. Owing to their proximity to the vital centres in the bulb these tumours share the fatal prognosis of other severe lesions of the posterior fossa. Hence removal by surgical methods offers the only hope of saving life and Professor Fraenkel and Dr. Hunt state that their necropsies have shown that in some cases such growths would be accessible to surgical operation and that trephining in any case, even when the tumour is inaccessible, would give considerable relief of symptoms. Of the five cases two were in males, aged 40 and 41 years respectively, and three were in females, aged 40, 42, and 51 years respectively, all Russians. The locality of the tumours was in all cases nearly identical—viz., the recess formed by the junction of the pons, bulb, and lateral lobe of the cerebellum. The certainty of localisation, the essentially benign nature of the growth, and the loose attachment of the tumours to the cerebral meninges and nerve trunks, conclude Professor Fraenkel and Dr. Hunt, distinguish this group of intracranial tumours as a most favourable one for surgical interference.

"THE WHITE MAN'S BURDEN."

THE acquisition of oversea dominions by the United States of America has had the effect of rapidly increasing the importance of several administrative problems. Questions of public health could not fail to be one of these, for the new possessions are entirely tropical and the political readjustments involve the maintenance of a considerable navy. It is true that most of the tropical diseases are found in the Southern States, although the coast-line, with New Orleans and Galveston as the chief towns, lies well to the north of the geographical limit of the tropics, but the loss by invaliding and deaths from disease among the national forces during and since the war with Spain has considerably enlightened the public mind as to some of the responsibilities which have been undertaken. An American Society of Tropical Medicine has been formed and its first public meeting was held at Houston Hall of the University of Pennsylvania, Philadelphia, on Jan. 9th, Dr. James M. Anders, a vice-president of the society, being in the chair. A brief statement of the scope and workings of the society was made by the secretary, after which the speaker of the evening, Dr. James Carroll, of the United States Army and a former member of the commission appointed by the Surgeon-General of the United States to investigate yellow fever at Havana, Cuba, gave an address upon the Etiology of Yellow Fever. Dr. Carroll reviewed in an interesting manner the early researches upon the etiology of the disease, giving special consideration to the work of Freire, Sanarelli, and Finlay; he then reviewed the work of the commission, the researches of which are now known everywhere, and maintained that there was no reason to believe that yellow fever was propagated by any other means than the bites of the mosquito known as stegomyia fasciata. It is only the female mosquito that bites; therefore it was only the female mosquito that became infected. The mosquito was able to impart the disease only after 12 days had elapsed since its own infection and might retain the ability to infect for many months provided that it did not meet with destruction in the meantime. He said that confirmation of all the work of the United States commission had been given by the more recently appointed French commission. The secretary of the society is Dr. Joseph McFarland, Medico-Chirurgical College, Philadelphia.

A CASE OF CYSTINURIA AND CYSTIN CALCULI.

Dr. E. Riegler of Jassy in Roumania records an interesting case of cystinuria in the *Medicinische Blätter* of Jan. 21st, p. 31. The patient was a young woman, aged 24 years, of emaciated appearance, who complained of severe headache, pains in the lumbar region, stomach, and bladder, and almost daily vomiting, with alternating diarrhœa and constipation. No evidences of organic disease were forthcoming after careful examination. The urine was turbid, neutral in reaction, yellowish-green in colour, with a specific gravity of 1010; it contained no albumin, casts, or other formed elements. Microscopical examination of the sediment showed typical hexagonal crystals of cystin. These crystals were dissolved by a watery solution of ammonia and were re-precipitated on dilution. Acetic acid added to the urine rendered clear by filtration produced a further crop of these crystals. An examination of the urine for diamines revealed the presence of considerable quantities of penta-methylene-diamine and tetra-methylene-diamine, as shown originally by Dr. E Baumann and Professor von Udranszky. The patient was then lost sight of owing to her departure from the town but four months later she returned with almost precisely similar symptoms, having been treated in the meantime by another medical man for catarrhal enteritis. The urine at this time was almost exactly identical with that on the previous examination save that no diamines could be found. Some days later the patient complained of severe pain in the bladder and urethra which on examination was found to be due to two calculi in the urethra. These were extracted and were found to be of yellow colour and slightly transparent; they were of about the size of cherries and could be scratched with the finger-nail. They were completely soluble in ammonia and on dilution of the solution typical hexagonal crystals of cystin separated out. A few small fragments of these calculi were heated with sodium hydrate and on cooling sodium nitroprusside was added, when a violet colouration was obtained. Dr. Riegler also found that if a few granules from a cystin calculus were treated with concentrated hydrochloric acid a fine felt-work of needles was at once formed which under the microscope was seen to be composed of long prisms which consisted of a compound of cystin and hydrochloric acid. One of the most interesting features of the case was the association of cystinuria with gastro-intestinal symptoms which Dr. Reigler attributed to fermentation processes in the intestine induced by micro-organisms, the diamines in the urine having a similar origin. On this supposition the treatment he adopted was to attempt disinfection of the alimentary canal by administering calomel for several days, followed by salol, naphthol, and chloroform water, large enemata of water being at the same time frequently given and the diet being restricted to milk with a little meat and vegetables. After two weeks the patient was relieved of all her symptoms. Cases of cystinuria are of sufficient rarity always to be worth recording. According to Dr. Baumann and Professor Goldmann very small quantities of cystin exist in normal urine. Since it contains sulphur it is almost certainly a derivative of the proteids of the food and tissues but the conditions of its formation are as yet little understood, though it has been suggested that it is a derivative of the taurin of the bile. Its occurrence is usually associated with the presence of diamines, though their absence in the present case at one stage indicates that the association is not invariable or essential.

"FILTHY LUCRE."

DIRT has its varying degrees of offensiveness which are very well illustrated in the current coins of the realm. The bronze penny may have easily detachable dirt adhering to it or it may be the kind of black dirt which commonly has for its basis greasy substances and which is not readily removed. The former is considerably more objectionable than the latter. The easily detachable dirt of the current coins comprises more or less wet or sticky substances derived during their transit through more or less dirty channels. The bronze coin doing duty in the public-house, for example, is frequently sticky from coming into contact with the swipes on the counter, the change from the butcher is often besmirched with something more offensive than fat, and the odorous trades, the fried-fish shop and the oil shop, leave evidence of their association upon the coin. All this is repugnant to cleanly disposed persons and the many possible dirty situations of a coin hardly bear reflection. We need not now insist on the possibilities of the coin as a spreader of disease, although bacteriology could easily sound an alarming note as to the pathogenic entities hidden in the crevices of a coin, for disease germs are likely to be found where money freely circulates. The bacteriological state of the pocket, by the way, might be worthy of investigation. It seems a pity that something cannot be done to prevent the wholesale distribution of filthy coins from such places as meat and fish markets. The bronze and silver money handed in bulk to the banks from the environment of Billingsgate or Smithfield, or even Covent Garden, is often in the most disgusting state and it is handed back again to the public in the same revolting condition. Surely where large parcels of coins are received smeared with the nastiest description of filth they might be washed or rinsed in hot water and soap before being distributed again to the public. The inventor who devises a cheap and handy machine for rapidly washing and scrubbing coins at the bank would be a public benefactor. Some pressure, we think, might be brought to bear upon the bank authorities in regard to this matter. All money systems of exchange, whether by means of coins or paper, are necessarily not quite in accord with the best interests of sanitation, but at least some steps might be taken which would prevent the circulation of coin in a grossly filthy condition.

CONGENITAL OCCLUSION OF THE ŒSOPHAGUS.

CONGENITAL abnormalities of the pharynx and œsophagus are of considerable interest to both the pathologist and the clinician. To the former they open up a fascinating field for speculation as to the mechanism of their causation. The cause once determined the possibility that developmental errors of a similar nature are agents in the production of obliterations, constrictions, and pouchings of other parts of the alimentary tract and also of parts of the arterial system at once presents itself. To the clinician the problem of exact diagnosis occurs and as a natural sequel the question as to whether cure or alleviation is within reach of the medical or surgical art. The contribution by Mr. W. Thomas in another part of our present issue cannot fail to be read with the greatest interest. The clinical picture which he draws is of the most striking character and it falls to the lot of but few of us to see such cases during life. The combination of vomiting, choking, inanition, and obvious hunger in a newly born infant such as he describes is apparently produced as the result of pharyngeal or œsophageal malformation and nothing else. Curious cases of choking induced by the swallowing of fluids have been described as occurring in the adult but here the causes are of different and diverse nature. The late Dr. J. S. Bristowe discusses such cases in his volume on Diseases of the Nervous System under the heading, "A Peculiar Form of Choking caused mainly by Swallowing Fluids." He also mentions an ingenious method of discovering the site of an abnormal communication between the air and food passages. The method consists in passing an œsophageal tube into the stomach and administering fluid through it whilst it is gradually withdrawn until the point is reached at which choking occurs. It is quite obvious, however, that in the case of the infants above mentioned the choking is due to overflow of the contents of the pouch above the stricture into the rima glottidis, the abnormal tracheal communication being below and not above the site of occlusion. Mr. Thomas indicates, and we think very properly, gastrostomy as the proper operation, combined with rectal feeding. The difficulties of any direct operation on the œsophagus must necessarily be almost insuperable and, moreover, in some instances the site of the fistula is as low down as the main bronchus. Any interference with the trachea at once increases the risks of broncho-pneumonia, risks which, from the nature of the choking, are already very great. These malformations have been extensively discussed by pathologists. They are mentioned and illustrated by Mr. J. Bland-Sutton in his work on Tumours and are discussed in a masterly manner by Mr. S. G. Shattock in the forty-first volume of the Transactions of the Pathological Society of London. Mr. Shattock's article will well repay perusal by those interested in the subject. He ascribes the malformations to the mechanical influence of the lung outgrowth from the primitive intestinal tube and brings forward considerable evidence in support of his contentions. Incidentally also he deals with certain malformations of the aorta which may have a somewhat similar mechanical origin.

TICK FEVER.

THE Treasury Department has issued from the Hygienic Laboratory Bulletin No. 14, by Dr. John F. Anderson, past assistant surgeon and assistant director, Hygienic Laboratory, United States Public Health and Marine Hospital Service (Washington, 1903). The subject of the bulletin is Spotted Fever (tick fever) of the Rocky Mountains. The disease has been known in the valley of the Bitter Root River in Western Montana for about 20 years and is sharply localised on the west bank of the river. It is also known to occur in Idaho, Nevada, Wyoming, and in a mild form in Oregon, but does not prevail south of 40° or north of 47°. It prevails at an average elevation of about 3000 to 4000 feet, exclusively in the spring and early summer, and among persons who follow occupations that cause exposure to the bites of ticks. To Wilson and Chowning belongs the credit of discovering an intracorpuscular parasite which is very probably the cause of the fever. Dr. Anderson saw the parasites under three forms: (1) the most common was a single ovoid body, refractile, and able to project pseudopodia; (2) a larger form, larger at one end and showing a dark granular spot, also amœboid; and (3) a form arranged in pairs, distinctly pyriform, with the smaller ends approaching. On a study of the cases of tick fever it was always found that there was a history of tick bites about one week before the onset. The ticks which are apparently necessary for the transmission of the disease belong to the genus dermacentor. The symptoms which follow the incubation of about seven days are for a few days chilly sensations, malaise, and nausea; finally there is a distinct chill and the patient takes to bed. There are pains in the head and back; soreness of the muscles and bones; constipation; tongue with heavy white coat, red edge and tip; conjunctivæ congested, becoming yellowish; urine scanty, with albumin and a few casts; slight bronchitis after a few days; and bleeding of the nose, sometimes quite severe, is always present. Before the distinct chill there is little or no fever in the morning, with a slight rise of temperature in the afternoon. After the chill there is an abrupt rise and then the fever gradually increases in the evening, with a slight morning remission. The maximum is usually reached on from the eighth to the twelfth day. The pulse-rate appears out of all proportion to the temperature, usually running from 110 to 140. Red blood counts show a progressive decrease in red cells. The white blood corpuscles are increased in number, a most interesting feature being an increase of the mononuclears. The eruption appears usually on the third day, first on the wrists and ankles, then on the arms, legs, forehead, back, chest, and, last and least, on the abdomen. At first the spots are bright red; they are macular and in size from that of a pin-point to that of a split pea. From about the sixth to the tenth day of the disease they fail to disappear on pressure and are distinctly petechial in character. When convalescence is advanced desquamation extends over the entire body. Of 121 cases which occurred in or near the Bitter Root Valley 84 patients died. Since the discovery of the parasite Dr. Wilson and Dr. Anderson suggested the use of quinine in large doses, preferably hypodermically. In five cases in which it was used recovery took place. Quinine bimuriate, one gramme, should be given every six hours hypodermically. The heart's power should be supported with strychnine and whisky. The patient should be encouraged to drink large quantities of water to flush out the kidneys. For the fever warm sponge baths or packs are useful and refreshing. Milk, broths, lightly boiled eggs, and soft toast may be allowed. As soon as a person is bitten by a tick the insect should be removed and the place cauterised with 95 per cent. carbolic acid. By applying ammonia, turpentine, kerosene, or carbolised vaseline the tick can usually be detached without trouble

HOMES FOR EPILEPTIC PATIENTS IN POOR CIRCUMSTANCES.

WE frequently receive inquiries from medical men who are endeavouring to find a home for some epileptic patient in poor circumstances. At present there is very limited provision for these distressing cases, but it may be convenient for our readers to mention some ways of dealing with them. The patients fall into two categories, those without mental impairment and those in whom there is temporary or permanent mental derangement. For the *sane* epileptics there are several excellent institutions.

1. The Colony for Epileptics at Chalfont, where provision is made for over 100 adult epileptics, both male and female, and also for children. Arrangements are made for educating the children and for employing the adults in market-gardeni[illegible] laundry work and other useful industrial occupations [illegible] patients [illegible] but a [illegible] are taken, for whom a pay[illegible] paid by [illegible] office [illegible] made [illegible] Gaskell.

[illegible] Home for Epileptics, Maghull, near Liverpool. This home has been open for 14 years and at the end of the year had 174 inmates. Like the Chalfont Colony the inmates are lodged in several homes on a farm and they are chiefly employed in out-of-door pursuits, such as market-gardening. At Maghull provision is made not only for working-class but also for second-class patients, and there is also limited private accommodation for first-class patients. The rates of payment are: working-class patients, 7*s* 6*d*.; second-class patients, £1 1*s*.; and first-class patients from £2 2*s* upwards, according to accommodation. Application has to be made to the honorary secretary, Mr. William Grisewood, Imperial-buildings, 2, Exchange street East, Liverpool.

3. The Meath Home of Com[illegible] Westbrook, Godalming, Surr[illegible] Hayling Island. Together th[illegible] The weekly rates of payment [illegible] patients and £1 1s for ladies. [illegible] for girls under 12 years of ag[illegible] tions should be made to the [illegible] the home.

4. [illegible] Warford, near [illegible] intended to [illegible] start will be [illegible] been decided [illegible] W. Marshall, [illegible]

All of these homes are managed by committees. Although they have all had munificent gifts in the way of land and buildings none of them are self-supporting and not only are there no free beds, but all of them require large annual subscriptions to maintain them efficiently. For the second group of patients, including those in whom there is mental impairment, it may be stated generally that they can only be provided for under the general arrangements for the insane. As the mental aberration is frequently temporary or occasional it is often a great hardship for the epileptic to be constantly housed with the insane. This has been recognised by the asylums committee of the London County Council which has provided the epileptic colony at Ewell for cases chargeable to one of the London county parishes. They are admitted either directly from their respective unions or transferred from one of the sister London county asylums. The cases admitted are able-bodied epileptics who are of unsound mind, not necessarily persistently so, but whose recurrent attacks are sufficiently frequent to demand their being under care. Recently arrangements have been made for setting aside a villa for the reception of male private cases at a weekly charge of 18s. for those who can claim a London settlement and £1 1s. for those who cannot. The present accommodation in the colony is for 266 males and 59 females. Applications should be sent to Dr. C. Hubert Bond, the medical superintendent at the colony.

TOXIC AMBLYOPIA CAUSED BY METHYL ALCOHOL.

AN important article dealing with the forms of blindness caused by the drinking of methyl alcohol or "wood spirit" is published by Dr. Frank Buller of the Victoria Hospital, Montreal, in the *Montreal Medical Journal* for January. Attention has been called from time to time in THE LANCET[1] to the dangers of methyl alcohol and of preparations containing large quantities of the same, either when drunk or accidentally inhaled. During the past decade, says Dr. Buller, literature has been much enriched by records of cases and by pathological studies of the toxic amblyopia caused by methyl alcohol. Since Rymovitch in 1896 showed that fatty degeneration of the retinal ganglion cells occurred in the case of rabbits posioned by methyl alcohol, others, and especially Ward Holden and Birch-Hirschfeld, have described the occurrence of chromatolysis, vacuolation and destruction of the cell bodies, and a varicose degeneration of the axons of the ganglion cells of the retina. The last-mentioned writer states that a close similarity exists between the lesions thus produced in rabbits and those occurring in cases of methyl alcohol intoxication in the human subject. The quantity of methyl alcohol required to produce blindness is variable. Five and a half drachms have produced severe headache, nausea, and vomiting. Doses of from two to eight ounces have produced severe, prolonged, and in some cases permanent blindness, and occasionally death has followed upon drinking two wineglassfuls of methyl alcohol. Of the cases recorded by Dr. Buller the following three may be cited. The first case was that of a woman, aged 34 years, who took one evening by accident a wineglassful of methyl alcohol instead of a dose of sarsaparilla which she had been in the habit of taking from time to time. On awakening next morning she experienced an intense headache, felt very ill and feeble, and to her great dismay was completely blind. The blindness lasted for two weeks, after which partial recovery of sight set in. No further improvement could be obtained after many more weeks of treatment, her eyesight being permanently enfeebled. The second case was that of a man, aged 39 years, who also accidentally took a wineglassful of methyl alcohol or "wood spirit" one evening. Next morning he awoke with an intense headache, marked diminution of sight, weakness, and inability to work. For a week his sight continued "blurred and foggy" while the margin of the field of vision was irregularly constricted. Some improvement then set in, followed by exacerbation of symptoms, and after the lapse of several months a permanent weakness and defectiveness of vision were present, including a blotting out of central vision. The third case was that of a man, aged 42 years, a carpenter by occupation, who took by accident "a small wineglassful" of wood spirit. Symptom of headache and loss of sight appeared the next day and a general dulness of visual acuity was the result. He was treated in hospital for several weeks and slight improvement followed. A general dulness of sight and a central scotoma, however, were permanently present. Dr. Buller points out that the degeneration of the retinal ganglion cells and nuclear layers affects firstly and chiefly the macular area or region of central vision, and diffusely also other parts of the retina, and that the consequent degeneration of the axis cylinders of these cells produces an axial neuritis in the optic nerve, a lesion from which recovery is practically impossible.

LEAD POISONING AND WATER-SUPPLIES.

IN a leading article in THE LANCET of Feb. 28th, 1903, p. 596, we dealt with the very valuable report which had then just been issued by the Medical Department of the Local Government Board on Moorland Waters in regard to their Action on Lead. This report gave details of a prolonged research undertaken by Dr. A. C. Houston which was based on the results of his systematic study of waters derived from a variety of moorland gathering grounds in Lancashire and Yorkshire. In a supplementary report issued last week Dr. Houston presents the results obtained from a prolonged and extensive series of laboratory experiments. We regard the results as of the utmost value. An enormous amount of experimental work has been done which should give considerable help in the future when difficulties arise in determining what are the chemical and biological factors concerned in producing acidity, ability to dissolve lead, or ability to "erode" lead pipes. The report is illustrated with several excellent plates demonstrating the effects of water under different conditions upon strips of sheet lead. It may be remembered that in his survey of the circumstances Dr. Houston referred to the importance of considering in detail the factors of "plumbo-solvency" in connexion with the presence of lead in moorland waters. He showed how it was advisable in the case of existing works to test the water not only in the reservoirs and main streams but also in the tributary streams and subsidiary "feeders" during different seasons of the year and under ordinary and extraordinary conditions of the rainfall in order to arrive at a satisfactory conclusion as to the liability of the supply in general and of its constituent waters to acquire "plumbo-solvent" ability. In this way the real remedy would probably picture which he draws is of the most striking character and it falls to the lot of but few of us to see such cases during life. The combination of vomiting, choking, inanition, and obvious hunger in a newly born infant such as he describes is apparently produced as the result of pharyngeal or œsophageal malformation and nothing else. Curious cases of choking induced by the swallowing of fluids have been described as occurring in the adult but here the causes are of different and diverse nature. The late Dr. J. S. Bristowe discusses such cases in his volume on Diseases of the Nervous System under the heading, "A Peculiar Form of Choking caused mainly by Swallowing Fluids." He also mentions an ingenious method of discovering the site of an abnormal communication between the air and food passages. The method consists in passing an œsophageal tube into the stomach and administering fluid through it whilst it is gradually withdrawn until the point is reached at which choking occurs. It is quite obvious, however, that in the case of the infants above mentioned the choking is due to overflow of the contents of the pouch above the stricture into the rima glottidis, the abnormal tracheal communication being below and not above the site of occlusion. Mr. Thomas indicates, and we think very properly, gastrostomy as the proper operation, combined with rectal feeding. The difficulties of any direct operation on the œsophagus must necessarily be almost insuperable and, moreover, in some instances the site of the fistula is as low down as the main bronchus. Any interference with the trachea at once increases the risks of broncho-pneumonia, risks which, from the nature of the choking, are already very great. These malformations have been extensively discussed by pathologists. They are mentioned and illustrated by Mr. J. Bland-Sutton in his work on Tumours and are discussed in a masterly manner by Mr. S. G. Shattock in the forty-first volume of the Transactions of the Pathological Society of London. Mr. Shattock's article will well repay perusal by those interested in the subject. He ascribes the malformations to the mechanical influence of the lung outgrowth from the primitive intestinal tube and brings forward considerable evidence in support of his contentions. Incidentally also he deals with certain malformations of the aorta which may have a somewhat similar mechanical origin.

10. This Act shall not extend to Scotland or Ireland.

11. This Act shall come into operation on the first day of January one thousand nine hundred and five.

12. This Act may be cited as the Revaccination Act, 1904.

SCHEDULE.

Table of Provisions of the Vaccination Acts, 1867 to 1898, which are Incorporated with this Act by and subject to the Provisions of Section 7 of this Act.

Session and chapter.	Short title.	Provisions incorporated.
30 & 31 Vict. c. 84.	The Vaccination Act of 1867.	Sections 10, 18, 20, 22 23, 24, 25, 26, 28, 29, 30, 31, 33, 34, and 35.
34 & 35 Vict. c. 98.	The Vaccination Act of 1871.	Sections 4, 5, 6, 7, 11, 12, 14, 15, 16, 17, and so much of the Schedule of Repeals as affects Section 23 of the Vaccination Act, 1867.
61 & 62 Vict. c. 49.	The Vaccination Act of 1898.	Section 2, Subsection (1), Sections 3, 5, 6, and 9, and so much of the Schedule of Repeals as affects Sections 20 and 29 of the Vaccination Act, 1867, and Section 11 of the Vaccination Act, 1871.

ELEVENTH ANNUAL REPORT (FOR 1902) OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON.

IN THE LANCET of Jan. 16th, p. 171, we inserted a short preliminary notice of Mr. Shirley Murphy's eleventh annual report to the London County Council. At the time of going to press the book had been in our possession only a few hours so that any detailed examination of its contents was for the time out of the question; it was therefore laid aside for subsequent treatment in a series of articles of which the present is the first.

The report before us is the eleventh of a series, each successive number of which, while preserving the necessary uniformity, has shown very distinct progress as compared with its predecessors. This volume, with its six appendices, runs to about 160 folio pages. Like its predecessors it is divided into three sections, the first of which deals mainly with vital statistics, the second with county sanitary administration, and the third contains, in the form of appendices, the reports of the several assistant medical officers on matters of hygienic importance that have been submitted to the chief medical officer in the course of the year.

Mr. Shirley Murphy opens his report with a review of the question of overcrowding as it affects London. It will be remembered that in the report for 1901 a table was published similar in form to that in the present report but based on the census returns of 1891. Owing, however, to the changes effected by the Local Government (London) Act of 1899 the areas of the London sanitary districts in the two tables do not admit of strict comparison, consequently a new table is now submitted which has been supplied by the Registrar-General and which shows particulars of occupation of tenements of less than five rooms at the date of the last census in the sanitary areas of the county as constituted prior to the passing of the Act just referred to.

The term "overcrowding," as used in this report, is applied to those tenements of less than five rooms, in each room of which at the census more than two persons were found to be living or sleeping. In view of the present controversy as to the housing of the London poor it is satisfactory to find from Mr. Shirley Murphy's report that in the county, as a whole, the proportion of the population occupying "overcrowded tenements" has declined from 19·70 to 15 97 per cent. within the last ten years. This decline appears to have been shared by the occupants of each class of tenement but it is most marked—as it is obviously desirable that it should be—in tenements limited to one or two rooms. It is in the case of such tenements, and especially in that of those consisting of single rooms, that the question of overcrowding becomes sanitarily of chief importance. We are therefore gratified to learn that the most conspicuous feature in the movement of the London poor for the last ten years is "the shifting of the people from tenements of one or two rooms to the more ample accommodation provided in tenements of three and four rooms." Moreover, we note that only in the sanitary areas of Whitechapel, St. George's-in-the-East, and Mile End Old Town, which have been specially affected by "alien" immigration, has there been an increase in the proportion of the total population occupying overcrowded tenements of less than five rooms. We further note that even in these areas the proportion of the population occupying overcrowded single-roomed tenements has declined.

This question of overcrowding in certain of the slum districts of the metropolis is of vital importance in its relation to the health of the people; and, if we mistake not, the information relating thereto now made public by Mr. Shirley Murphy will be duly appreciated by the committee which is at present considering the subject of the alleged physical deterioration of the labouring classes.

In many of his past annual reports the county medical officer has directed attention to the almost continuous decline that has taken place in the birth-rate of London. Ever since the decade 1881–90, when the rate averaged 33·2 per 1000, there has been (with some few intermissions) a steady decline in the ratio of births to population. In 1902 the rate was only 28·5 and was the lowest since the institution of civil registration. In England and Wales generally there has likewise been a steady decline in the birth-rate since the decade just mentioned, but in that case the lowest rate recorded was that of 1901, a slight recovery having taken place in the rate of the following year.

As the London marriage-rate—i.e., the proportion of persons married to population—was higher in 1902 than in the preceding year it may reasonably be hoped that the returns for 1903, when they are available, will show a corresponding improvement in the birth-rate.

Coming now to speak of London mortality in the year 1902, we find that, as in recent past years, elaborate precautions have been taken to avoid fallacies arising from the use of crude rates of mortality—i.e., the mere proportions of deaths to persons living without correction either for deaths in public institutions or for differences in the composition of the population as regards age and sex. A table is given in the present report showing the death-rate of London for decennial periods from 1841–50 to 1881–90, and also for separate years from 1891 down to the present date. With respect to the latter series of years (though not to the decennial periods) it should be noted that the rates are fully corrected for institution mortality, i.e , by *excluding* the deaths of persons not belonging to but occurring in institutions situated within the county of London and by *including* the deaths of persons belonging to London but occurring in London institutions situated outside the administrative county. So likewise in dealing with the death-rate of the separate sanitary areas of London: for in his remarks on the mortality of the London boroughs Mr. Shirley Murphy is careful to state that the several published rates *include* the deaths of Londoners in the metropolitan workhouses, hospitals, and lunatic asylums outside the county, but *exclude* the deaths of non-Londoners in the Willesden Workhouse, the London Fever Hospital, the Metropolitan Asylums Board hospitals, and the Middlesex county asylums, all of which institutions are situated within the administrative county of London. In this way a degree of correction has been applied to the London death-rate which approaches completeness perhaps as nearly as possible under existing conditions of life. Perfection in this respect is, for obvious reasons, unattainable, for the deaths of strangers taking place in private houses within the metropolis cannot be extracted from the local death registers, neither can account be given of the deaths of Londoners occurring away from home; but we wish we could assume that the death-rates of all other English municipalities were corrected with equal completeness and care, for in that case statisticians would attach much greater importance to the comparative statements of local mortality than that which they are at present held to deserve. The general death-rate of London in the year 1902 was equal to 17·2 per 1000 persons living at all ages and of both sexes. It was therefore higher by 0·1 only than the rate of the year immediately preceding and with this exception was the lowest rate hitherto recorded for the metropolis as a whole. A useful chart is appended to this section of the report which illustrates graphically, and therefore to most persons more clearly than tabular statements can do, the curve of London mortality in recent and previous years, the rates for the last 60 years being shown in relation to a mean line represented by the rate of 22·4 per 1000. This chart indicates that, disregarding a few earlier years in which there have been oscillations above and below this mean, the death-rates since the year 1880 have been below, and, speaking generally, increasingly below, the mean line On the other hand, the rates in the years prior to 1880 were in most cases very considerably above the average. Comparing with the London death-rate the death-rates of those of the great towns of England which contain more than 200,000 inhabitants, as given in the weekly, quarterly, and annual returns of the Registrar-General, it is found that London had in 1902 a lower rate than Manchester, Liverpool, Birmingham, Leeds, Salford, and Newcastle, and in the decennium 1892–1901 had a lower rate than any of these towns except Bristol, Nottingham, Hull, West Ham, and Leicester. Comparing the London death-rate with that of the principal continental towns, as given in the Registrar-General's returns, it is shown that both in the period 1892–1901 and in the year 1902 the London rate exceeded that of any of these towns except Paris, St Petersburg, Vienna, Rome, and New York. A table is given showing the corrected rates of mortality in each of the metropolitan boroughs, a second shows the number of deaths occurring at the usual age groups, and a third gives the mean death-rates obtaining in London at the several age periods and for each sex in the ten years 1891–1900 and in the year 1902. The figures for the year 1902 are fully corrected for institution deaths and the rates for the period 1891–1900 are based upon figures which have been corrected for institution deaths on the basis of the experience of the four years 1897–1900.

In a footnote to the first of these tables Mr. Shirley Murphy observes: "A few of the age and sex factors shown here differ materially from the corresponding factors published in my last annual report. This is due to the fact that since the publication of my last report I have been able to obtain from the General Register Office the age and sex distribution of the population of several large workhouses and infirmaries which are situated outside the area from which their inmates are drawn, and the populations of these institutions have been added to the populations to which they properly belong and the factors recalculated." If the death-rate of London be taken as 1000 the death-rate of its several boroughs range from the lowest—669 in Hampstead and 773 both in Stoke Newington and in Lewisham—to the highest—1304 in Holborn and 1320 in Finsbury.

(*To be continued*)

AT the meeting of the Quain Society to be held in the anatomical theatre, University College, London, W.C., on Monday evening, Feb. 8th, at 8 o'clock, Sir Victor Horsley will read a paper, illustrated with photographs and lantern slides, on the Termination of the Fillet in the Optic Thalamus. Visitors are cordially invited.

Looking Back.

FROM

THE LANCET, *SATURDAY*, FEB. 4, 1826.

REVIEW.[1]

The Science of Surgery, or the Principles of Pathology made the basis of Medical and Surgical Practice. By W. W. SLEIGH, Esq., Lecturer on Anatomy, Physiology, and Surgery. 8vo. pp. 316 London, 1825 Anderson. Vol. I.

We are next presented with the case of the late Lord Byron, which the author has transcribed from the account given by Count Petro Gambia.

"April 9th, Lord Byron had suffered visibly in his health during the last day or two: the events just mentioned, and the weather, had made him more than usually nervous and irritable; but he this morning received letters from Zante and from England, which raised his spirits exceedingly. He had not been on horseback for three or four days; and though the weather was threatening, he resolved to ride. Three miles from the town we were overtaken by a heavy rain, and we returned to the town walls wet through, and in a violent perspiration. Two hours after his return home, he was seized with a shuddering: he complained of fever and rheumatic pains. At eight in the evening I entered his room; he was lying on a sofa, restless and melancholy. He said to me, I suffer a great deal of pain; I do not care for death; but these agonies I cannot bear. The medical men proposed bleeding, but he refused, observing, 'Have you no other remedy than bleeding?—There are many more die of the lancet than the lance.' Some of the physicians answered, that it was not absolutely necessary to bleed as yet, and I fear were too much inclined to flatter his prejudice against that operation. But there was not then the slightest suspicion of any danger, nor was there any at that moment.

10th. The next day he felt himself perpetually shuddering; but he got up at his usual hour, and transacted business; but he did not go from home.

12th. The next day he kept his bed with an attack of rheumatic fever.

13th. He rose from his bed the next day, but did not go out of the house. The fever appeared to be diminished; but the pains in his bones and head still continued: he was melancholy and very irritable. He had not been able to sleep since his attack, and he could take no other nourishment than a little broth, and a spoonful or two of arrow-root.

14th. The following day he got out of bed at twelve: he was calmer; the fever was less, apparently, but he was very weak, and suffered from the pains in his head. He wished, however, notwithstanding the weather was threatening, to go out on horseback, or at least in a boat; but his physicians dissuaded him. It was now thought that his malady was got under, and that in a few days he would be quite recovered. There was no suspicion of danger.

15th. The fever was still upon him; but the pains in his head and bones were gone. He was easier: he even wished to ride out; but the weather would not permit. Both on this day and the day before, he had entertained some suspicions that his complaint was of no ordinary nature, and that his physicians did not understand it; but he had not the least apprehension of danger.

16th. He was better; his complaint was following the usual course, and there was no fear.

17th. The next day I contrived to get to his room. His countenance at once awakened the most dreadful suspicions: he was very calm; he talked to me in the kindest manner. This was the first day that the medical men seemed to entertain serious apprehensions of the event: he was bled twice; first in the morning, and at two in the afternoon, and lost about two pounds of blood. He did not faint, and his eyes were lively, but he had no sleep; he perspired on the head and neck: and the disease seemed attacking the head. He was dreadfully distressed by want of sleep; and he now said to Dr. Millingen, 'I know that without sleep, a man must die or go mad: I would sooner die a thousand times.' He repeated this to his valet Mr. Fletcher.

18th. During the night of the 17th, he had some attacks of delirium, in which he talked of fighting; but neither that night nor the next morning was he aware of his peril. This morning his physicians were alarmed by appearances of inflammation of the brain, and proposed another bleeding, to which Lord Byron consented, but soon ordered the vein to be closed. Dr. Bruno entreated him, with tears in his eyes, to be again bled. No, he said: if my hour is come, I shall die whether I lose my blood or keep it.

Since their last consultation, the majority of the medical men had thought that the crisis of the disorder was now come, and that the principal danger now was the extreme weakness of the patient; and that restoratives should be administered. Dr. Bruno thought otherwise; but it was resolved to give a draught of claret and bark and opium, and to apply mustard blisters to the soles of the feet. Byron took the draught readily, but refused the blisters: accordingly I was sent for to persuade him, and I returned in all haste with Mr. Parry.

It was about six o'clock in the evening when he said—I want to go to sleep now; and immediately turning round, he fell into that slumber, from which, alas! he never awoke!

On my arrival, they informed me that he was asleep, and that he had suffered the blisters to be applied, not to his feet but elsewhere. The physicians augured well of this sleep—perhaps it was but the effect of the medicine, and only hastened his death."[2]

MIDWIVES IN THE RURAL DISTRICTS.

THE conference convened by the Rural Midwives' Association was held on Jan. 27th at 3, Grosvenor-place, London, S.W., to consider plans to meet the requirements of the Midwives Act in the various rural and provincial districts, including the training and supervision of midwives, assistance from local associations, and other points connected with the work. The chair was taken by Lord Belper, vice chairman of the County Councils' Association. After two hours' discussion the conference came to the unanimous conclusion that the requirements of the Midwives Act might be usefully met by adding midwives to the staffs of the local nursing associations and by training local women to work under a small committee, provided that in both cases their work was kept distinct from cases dangerous to their calling. Where localities were unable to meet the initial expense of training midwives it was considered that recourse must be had to grants from county councils and others but some payment by the patient ought always to be made to meet the current expenses. The conference further expressed its opinion that respectable women of the cottager class, carefully trained and working under supervision, would meet the requirements of the Act in rural districts. The last formal declaration of the conference was that the supervision of the local committee was advisable in every case and that it should be in communication with the local supervising authorities under the Act. Dr. R. Boxall said that to avoid pauperising the class of people who used midwives a plan should be adopted by means of which they should contribute some small sum to an institution for the payment of a medical man if required. He considered it a very detrimental practice to leave it to the midwife to call in a medical man when she thought it necessary and to reduce her fee when that occurred. He advised that the best of the women of the cottage class who had been already working as midwives in the rural districts should be sought out and put through a suitable training. Dr. W. S. A. Griffith, physician to Queen Charlotte's Hospital, pointed out that the work of the association was to assist in training the midwives who were to practise in the rural districts. These women would be poorly trained and quite unable to pay for their own training or to make a living from midwifery unless they had homes of their own and were independent of their earnings. The association must not place a strange midwife in a district and tell the people to go to her. They must take a woman from the district, train her, and then let her work among those who know her. Midwives for the rural districts must be trained in some less expensive method than obtained in the great metropolitan hospitals and yet they must be taught up to the standard of the Midwives Board. In his opinion the combination of elementary nursing, sanitation, cooking, with the preparation required from midwives, was the training at which the Rural Midwives' Association and all similar bodies should aim. Dr. F. R Cassidi of Derby gave an account of how they managed to set on foot a scheme for the training of midwives for the rural districts at the cost of about £20 for a year's training. One of the ladies present spoke of the success achieved in her district by supervising the work of the midwives through a local committee. Her remarks were met by another lady from Scotland who said that her experience was that the midwives were apt to supervise the local committee and in the particular case to which she referred the difficulty was met by appointing a fully trained and certificated nurse to superintend the work of the midwives, a plan which answered admirably. Dr. Constantine Holman in a few words persuaded the meeting to take his view that it was most certainly advisable to recommend that local committees should be intrusted with the supervision of the work in question.

[2] The appearances on dissection also are set out in THE LANCET of Feb. 4th. 1826.

ASYLUM REPORTS.

Hereford City and County Asylum, Burghill (Report for the year ending March 31st, 1903).—The average number of patients resident during the year was 453, comprising 204 males and 249 females. The admissions during the year amounted to 161—viz., 67 males and 94 females. Of these, 109 were first admissions. Mr. C. S Morrison, the medical superintendent, states in his report that among the causes of insanity in the admissions were senile decay, neuropathic heredity, and alcoholic intemperance in descending order of frequency. "The remarks that have been made in previous years," adds Mr. Morrison, "as to the unfavourable type of admissions in regard to prospect of recovery may be repeated." The tendency among parochial officials and authorities to send to the asylum persons of unsound mind, especially those suffering from bodily disease and infirmity rather than serious mental disorder, shows no diminution. Of the patients admitted during the four years 1900–03 "109 were from 60 to over 80 years of age, the great majority requiring infirmary care and treatment." The number of patients discharged as recovered during the year amounted to 29, comprising 15 males and 14 females, or 6·4 per cent. of the average number resident. The deaths during the year amounted to 38, or 8·3 per cent. as calculated on the same basis. Of the deaths, two were due to epilepsy, two to pulmonary tuberculosis, three each to cancer and general paralysis, five each to bronchitis, cardiac disease, and senile decay, and the rest to other causes. An epidemic of scarlet fever occurred in the institution and affected 12 patients (six males and six females), 16 nurses, and two attendants. "That we had no death from scarlet fever was fortunate, especially as the majority who suffered were the younger members of the staff." Electric lighting was decided upon as best for the purposes of the institution and an electric installation has since been put up throughout the building. The Commissioners in Lunacy state in their report that all parts of the asylum were found to be in good order, that the wards were bright and cheerful, that the dormitories and bedding were clean, well ventilated, and well-cared for, that the patients seemed comfortable and contented, and that the medical case-books were well kept. The committee of management states in its report that the farm and dairy are in a satisfactory condition and draws attention to "the gradual extermination of tuberculosis in the herd of dairy cows which has never been healthier than at present." In consequence of the increased number of patients under care the committee has found it necessary to appoint a third medical officer to the institution.

Wilts County Asylum (Report for the year ending March 31st, 1903).—The average number of patients resident during the year was 938, comprising 425 males and 513 females The admissions during the year amounted to 162—viz., 73 males and 89 females. Of these 137 were first admissions. Mr. J. Ireland Bowes, the medical superintendent, states in his report that the number of hopeless and incurable cases among the admissions continued to increase yearly, particularly as unions no longer afforded the relief that they did years ago. Hereditary predisposition and alcoholic intemperance were among the most important causes of insanity in the admissions. 15 were epileptics and a large proportion were said to have made attempts at suicide. The number of patients discharged as recovered during the year amounted to 45—viz, 15 males and 30 females, or 4·8 per cent. of the average number resident. The deaths during the year amounted to 70, or 7·4 per cent. as calculated on the same basis. Of the deaths three were due to cerebral softening associated with hemiplegia, three were due to bronchitis, four to epilepsy, eight to senile decay, ten to general paralysis of the insane, 13 to cardiac disease, 17 to pulmonary and other forms of tuberculosis, and the rest to other causes. The cause of death was verified by post-mortem examination in 54 cases. A male patient suffering from delusions of persecution secretly secured possession of an old razor thoughtlessly left in an unlocked drawer in the room of a junior attendant and with this instrument he made a murderous attack on a fellow patient whose throat he attempted to cut when his victim was asleep. The injury was serious but did not prove fatal. The health of the institution has been good throughout the year apart from the occurrence of isolated cases of dysentery and erysipelas. The Commissioners in Lunacy state in their report that the wards were bright, cheerful, and clean, that the dormitories were well ventilated, that the patients seemed physically in good health and fair condition, and that the medical case-books and records were particularly well kept. The committee of management states in its report that a new detached block for female patients is in process of erection and that a new waiting room and the isolation hospital have been completed during the year. Owing to the continued high price of most necessaries used at the asylum and to the increase in the rates the committee was obliged to raise the weekly rate of maintenance per patient to 10*s.* 6*d.*, as against 9*s.* 11*d.* during the previous year.

MEDICINE AND THE LAW.

The Cold Weather and the Factory Acts.

A COMPANY called the Eburite Paper Company, 35, Red Lion-street, was fined £10 and 18*s.* costs at Bow street police-court on Jan. 22nd for failing to take measures for securing a reasonable temperature in its workrooms. On Dec. 31st, 1903, when, it will be remembered, there was a spell of extremely cold weather, Miss Vines, a factory inspector, found women and girls at work in rooms upon the company's premises, two of which were at 42° F. and one at 45°. The magistrate, Mr. Fenwick, characterised the offence as a bad one of its kind, which it certainly was, and imposed further penalties of 40*s.* upon the same defendants upon each of three summonses for employing girls under 16 years of age without medical certificates of their fitness for employment in the factory.

Street Locomotives.

Attention was recently called in THE LANCET to the increased number of locomotives to be seen and, at night, heard drawing trucks through the London streets, to the heavy weights allowed to be treated thus, and to the annoyance and disturbance caused by the resulting noise and vibration. Driven by sober men these engines are terrifying to horses and consequently dangerous both to persons driving and to foot passengers. A man in charge of such an engine drawing a truck behind it was recently stopped by a policeman after he had driven on the wrong side of a street refuge and had proceeded on his way at a rate described as about seven or eight miles an hour. He was sentenced at Clerkenwell police-court on Jan. 21st to a month's imprisonment and may consider himself lucky that he is not lying under remand on a charge of manslaughter.

Corporal Punishment and Crimes against Women.

Grand juries frequently make "presentments" at country assizes recommending legislation to enable rape and kindred offences to be punishable by flogging, and this penalty was actually ordered to be inflicted by Mr. Justice Darling in a recent case upon the Western Circuit where the prisoner, by pleading guilty to an indictment charging him with robbery with violence, enabled the learned judge to take advantage of the law passed with a view to garotting. The prisoner, a labourer, aged 27 years, and married, pleaded guilty to three indictments charging him with an assault with intent to ravish committed upon one woman, with an indecent assault committed upon another, and with using personal violence to a third and robbing her of 12*s.* Three other women had identified him as having indecently assaulted them and the police at Bournemouth had had many complaints of similar acts committed in the same neighbourhood which had ceased since his arrest and imprisonment. In sentencing him to receive 24 lashes with the cat and to be imprisoned for six months the judge made it abundantly clear that it was for the offences of lust that he was ordering personal chastisement and not for the robbery for which technically it was to be inflicted. Many will approve of the course taken but at the same time there is another side to the question and the fact that the prisoner had had six months' imprisonment before for an assault upon a girl at Bournemouth, coupled with the series of disgusting and cruel outrages perpetrated upon women in the same locality, go to show a condition of mind inconsistent with perfect sanity. Moreover, it was proved that on one occasion the man was actually arrested by the Bournemouth police and charged with being a wandering lunatic, and although the medical evidence on that occasion did not justify his certification and detention mental conditions change rapidly, and the arrest upon the charge of insanity shows, at any rate, the view held as to his condition by those who then took him into custody. The carrying out of a sentence of severe corporal punishment upon a man mentally defective is undesirable from the point of view of humanity and the release of a man with an insane tendency to attack females after six months in prison and a flogging is hardly to be recommended in the interest of the public unless it is consider [illegible] inflicted will deter him from [illegible] worse crimes in the future. [illegible] would seem to demand at all events careful consideration on the part of judges with the assistance of evidence given by medical men of experience in such matters. On the other hand, a case which has just been tried by Mr. Justice Phillimore on the North Wales Circuit presents features which seem to demand corporal punishment if such a penalty is ever to be inflicted. In this instance three young colliers set upon a woman, 60 years of age, after dark, knocked her about, stripped her, outraged her, and tortured her. The judge characterised it as the worst case that he had ever tried and sentenced two of the ruffians to 12 years' penal servitude and the third to 15 years. In rape by a gang there can hardly be a question of the prisoners' mental responsibility and if a flogging had been ordered in the case of the three Welsh colliers few could be found to protest on grounds of humanity or justice.

Corporal Punishment in Board Schools.

The head-master of a board school at Hackney was recently fined 40*s.* with 23*s.* costs by Mr. Fordham for inflicting upon a pupil a caning which, in the opinion of the magistrate, was excessive although he had no doubt that the boy was disobedient and defiant. It appeared that there had been to begin with a dispute between the boy and an under-master as to whether the former deserved a minor punishment and resentment on the one side coupled with a determination to enforce submission on the other led to about 20 strokes being eventually inflicted. Whether great force was used or not there was medical evidence of considerable bruising given by Dr. Leslie Durno whose experience as divisional surgeon of police would not be likely to cause him to take a sentimental view. It is, however, to be said that the buttocks are very easily marked by blows which otherwise leave little after-effect. Many men must now occupy positions as magistrates or school-masters who have in years almost forgotten by them played their usual games as schoolboys within a day or two after receiving punishment quite unconscious of backs which would have excited the horror and indignation of their female relatives. Mr. Fordham disclaimed all sympathy with the modern sentiment against corporal punishment in schools but no doubt was of opinion that there had been loss of temper caused by the obstinacy of an unruly boy rather than due recognition of a breach of discipline. With the difficulties under which board school teachers enforce discipline in the absence of all home training the public should fully sympathise. The minor punishment which the boy refused to submit to in the case before Mr. Fordham would have consisted of two "handers." Blows on the hand are far more likely to occasion injury than those on portions of the frame which, though sufficiently sensitive, are better adapted by nature to the purposes of chastisement and it would be interesting to know the precise nature of the "hander" intended to be given.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMITIA was held on Jan. 27th, Sir WILLIAM SELBY CHURCH, Bart., K.C.B., the President, being in the chair.

The following gentlemen having passed the required examination were duly elected and admitted as Members of the College: Sol Jervois Aarons, M.D. Edin.; David Forsyth, M.D. Lond., L.R.C.P. Lond.; Alfred Ernest Jones, M.D. Lond., L.R.C.P. Lond.; and Lindley Marcroft Scott, M.A., M.D. Aberd.

Licences to practise medicine were granted to 112 gentlemen who had passed the required examinations.

Diplomas in Public Health jointly with the Royal College [illegible] re granted to the following [illegible] Edmund Bridger, L.R.C.P. [illegible] n Caddy, M.D., B.S. Lond., L.R.C.P. Lond., M.R.C.S. Eng.; Alfred George Caldwell, M.D., B.Ch. R.U.I.; John William Edward Cole, B.C. Cantab., L.R.C.P. Lond., M.R.C.S. Eng.; Beaumont Harry Comerford, L.R.C.P. Lond., M.R.C.S. Eng.; Archibald Sinclair David, L.R.C.P. Lond., M.R.C.S. Eng.; Arthur Sydney Downton, L.R.C.P. Lond., M.R.C.S. Eng.; Leslie Winter Dryland, L.R.C.P. Lond., M.R.C.S. Eng.; Gilbert Elliott, L.R.C.P. Lond., M.R.C.S. Eng.; Alexander Robertson Falconer, M.B., B.Ch. New Zealand; Major Ernest Carrick Freeman, R.A.M.C., L.R.C.P. Lond., M.R.C.S. Eng.; Gerald Dudley Freer, M.B. Lond., L.R.C.P. Lond., M.R.C.S. Eng.; David Arthur Hughes, L.R.C.P. Lond., M.R.C.S. Eng.; Major Malcolm Albert Ker, I.M.S., M.B., C.M. Edin.; John Everard Linnell, M.B., B.C. Cantab.; Brinley Richard Lloyd, L.R.C.P. Lond., M.R.C.S. Eng.; Sidney Isaac Pritchett, L.R.C.P. Lond., M.R.C.S. Eng.; Charles Ryley, L.R.C.P. Lond., M.R.C.S. Eng.; Major Arthur Ernest Smithson, R.A.M.C., M.B., B.C. Cantab., L.R.C.P. Lond., M.R.C.S. Eng.; Percy Taylor Humphrey Stedman, M.B. Lond., L.R.C.P. Lond., M.R.C.S. Eng.; Arthur Hitchings Thomas, L.S.A.; George Smith Wallace, M.B., Ch.B. Glasg.; and Edward Croft Watts, M.D., C.M., F.R.C.S. Edin.

The PRESIDENT announced that Dr. E. Klein had been appointed to deliver the first Dr. Horace Dobell lecture in November of this year. Also that Dr. J. F. Payne would deliver the FitzPatrick lecture probably on Nov. 8th or 10th of this year.

The following communications were received:—1. From Dr. Hugh Walsham, asking leave from the College to publish his Weber-Parkes prize essay. Permission was granted. 2. From Dr. George Oliver, offering to present £2000 to the College in trust to endow a lectureship or prize, with a view to encourage the application of physiological knowledge to the prevention and cure of disease and the prolongation of life. The terms of the trust were given and the award will be termed the "Oliver-Sharpey Prize," according to the desire of the donor. The thanks of the College were returned to Dr. Oliver for his liberality, his offer having been gratefully accepted. 3. From the secretary of the Physical Deterioration Committee of the Privy Council, asking the College to nominate a physician to give evidence before it. A further communication contained a request that a physician should be nominated to give evidence on the occurrence of lunacy amongst the poorer classes. Dr. Eustace Smith, Dr. H. Ashby, and Dr. R. Hutchison were nominated to give evidence on matters connected with physical deterioration and it was left to the President to nominate a physician to give evidence on the occurrence of lunacy. 4. From the President of the General Medical Council, asking the opinion of the College on certain questions raised by the report of the visitors on the whole series of first examinations of the licensing corporations inspected. The matter was referred to the committee of management.

The College seal was set to a "declaration of trust," accepting on the part of the College a sum of £500 Consols in trust to endow for a term of years a lectureship at the College to be called "The Dr. Horace Dobell Research Lectureship," the conditions having been already agreed upon.

Dr. E. Markham Skerritt, Dr. Samuel H. West, Dr. J. Abercrombie, and Dr. J. Kingston Fowler were appointed Councillors, and it was further resolved that Dr. P. H. Pye-Smith should remain on the Council for a second period of two years.

It was announced that the Council had appointed Dr. T. M. Legge, one of His Majesty's inspectors of factories, to be Milroy lecturer for 1905. The subject of the lectures will be Industrial Anthrax.

A report, dated Dec. 17th, 1903, was received from the committee appointed on July 2nd, 1903, on the Physical Disability of Army Recruits. The committee had considered a communication received from the Director General of the Army Medical Service and the following motions had been adopted:—

> The committee of the Royal College of Physicians appointed by the College, July, 1903, having taken into consideration the further documents submitted to them, are of opinion that an inquiry into the present extent and causes of the alleged physical disability for military service of certain classes of the population is desirable.
>
> In their former report the committee considered that sufficient data were not available for forming a judgment on the extremely complex question of the occurrence or not of progressive degeneration in the classes from which recruits are mainly drawn, and the supplementary matter now brought before them does not suggest any modification of their former opinion.

A report was received from the committee appointed on Oct. 29th last to consider a Norwegian report on beri-beri occurring on board ships submitted by the Board of Trade. The report was adopted as the answer of the College to the Board.

A report was received and adopted from the representative of the College (Dr. Norman Moore) on the General Medical Council on the proceedings of the Council affecting the College at its session in November last.

The quarterly report of the College finance committee was received and adopted.

A report was received from the committee of management, dated Dec. 7th, 1903. The committee recommended that the municipal schools at Gloucester should be added to the list of institutions recognised by the Examining Board in England for instruction in chemistry, physics, and practical chemistry. The report was adopted.

A report was received and adopted from the laboratories committee, dated Dec. 4th, 1903.

Books and other publications presented to the library during the past quarter were received and thanks were returned to the donors.

The annual returns by the examiners of the results of the examinations for the Licence in the year 1903 were received.

The PRESIDENT then dissolved the Comitia.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8512 births and 5669 deaths were registered during the week ending Jan. 30th. The annual rate of mortality in these towns, which had been 20·3, 19 0, and 18 1 per 1000 in the three preceding weeks, rose again last week to 19·4 per 1000. In London the death rate was 19·5 per 1000, while it averaged 19·3 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 6·4 in Hornsey, 8 6 in Hastings, 9·4 in King's Norton, 10 4 in Wallasey, 11·4 in Willesden, 12·0 in Northampton, and 12 2 in Leyton. The 5669 deaths in these towns last week included 497 which were referred to the principal infectious diseases, against 462, 450, and 427 in the three preceding weeks; of these 497 deaths 167 were referred to whooping-cough, 114 to measles, 77 to diphtheria, 70 to diarrhœa, 39 to scarlet fever, 28 to "fever" (principally enteric), and two to small-pox. No death from any of these diseases was registered last week in Hornsey, Hastings, Bournemouth, Southampton, Burton-on-Trent, King's Norton, Smethwick, Barrow-in-Furness, or Tynemouth, while the highest death-rates from the principal infectious diseases were recorded in Great Yarmouth, Walsall, Warrington, Bury, Preston, West Hartlepool, Rhondda, and Swansea. The greatest proportional mortality from measles occurred in Warrington, Bury, Rochdale, Blackburn, Preston, Leeds, and Cardiff; from scarlet fever in Devonport and Walsall; from diphtheria in East Ham, Walsall, Aston Manor, and St. Helen's; from whooping-cough in Great Yarmouth, Coventry, Bolton, Bury, West Hartlepool, Gateshead, Merthyr Tydfil, and Swansea; from "fever" in Devonport, Walsall, and Rhondda; and from diarrhœa in Preston. Of the two fatal cases of small-pox registered in these towns last week one belonged to Manchester and one to Gateshead. The Metropolitan Asylums hospitals contained 21 small-pox patients on Saturday last, Jan. 30th, against 26, 26, and 24 on the three preceding Saturdays; four new cases were admitted during last week, against six, four, and three in the three preceding weeks. The number of scarlet fever cases remaining under treatment in these hospitals and in the London Fever Hospital, which had been 1659, 1660, and 1677 at the end of the three preceding weeks, had declined again to 1651 at the end of last week; 168 new cases were admitted during the week, against 201, 195, and 180 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 433, 406, and 353 in the three preceding weeks, rose again last week to 429, and were 74 above the number in the corresponding period of last year. The causes of 87, or 1·5 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bolton, Leeds, Newcastle-upon-Tyne, Cardiff, and in 39 other smaller towns; the largest proportions of uncertified deaths were registered in Willesden, Reading, Birmingham, Smethwich, Coventry, Liverpool, Bootle, Manchester, Sheffield, Sunderland, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 23·2, 20·2, and 19·8 per 1000 in the three preceding weeks, further declined to 18·4 per 1000 during the week ending Jan. 30th, and was 1 0 per 1000 below the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 11·2 in Greenock and 14·3 in Aberdeen, to 18·8 in Leith and 31·3 in Dundee. The 608 deaths in these towns included 17 which were referred to diarrhœa, 16 to whooping-cough, 12 to measles, seven to diphtheria, six to scarlet fever, three to small-pox, and one to "fever." In all 62 deaths resulted from these principal infectious diseases last week, against 53, 63, and 54 in the three preceding weeks. These 62 deaths were equal to an annual rate of 1·9 per 1000, which was 0 2 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 15, 13, and 14 in the three preceding weeks, further rose last week to 17, of which eight were registered in Glasgow and seven in Dundee. The deaths from whooping-cough, which had been 15, 15, and 11 in the three preceding weeks, rose again to 16 last week, and included four in Aberdeen, three in Edinburgh, three in Dundee, and three in Leith. The fatal cases of measles, which had been 13, 23 and 19 in the three preceding weeks, further declined last week to 12, of which six were registered in Glasgow, three in Dundee, and two in Paisley. The deaths from diphtheria, which had been three in each of the three preceding weeks, increased to seven last week, and included five in Glasgow. The fatal cases of scarlet fever, which had been one in each of the three preceding weeks, rose last week to six, of which three occurred in Glasgow. The deaths from small-pox, which had been three, five, and two in the three preceding weeks, increased again to three last week, and were all recorded in Glasgow. The deaths referred to diseases of the respiratory system in these towns, which had been 213, 198, and 167 in the three preceding weeks, further declined last week to 128, and were 45 below the number in the corresponding period of last year. The causes of 20, or more than 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 27·8, 28·8, and 26·0 per 1000 in the three preceding weeks, further declined to 25·6 per 1000 during the week ending Jan. 30th. During the past four weeks the death rate has averaged 27 1 per 1000, the rates during the same period being 18 8 in London and 17 9 in Edinburgh The 186 deaths belonging to Dublin registered during the week under notice, showed a decline of three from the number in the preceding week and included 14 which were referred to the principal infectious diseases, against 23, 10, and eight in the three preceding weeks; of these, 11 resulted from whooping cough, one from measles one from "fever," and one from diarrhœa, but not one from small pox, from scarlet fever, or from diphtheria These 14 deaths were equal to an annual rate of 1 9 per 1000 the death rates last week from the principal infectious diseases being 1 5 in London and 0 9 in Edinburgh The fatal cases of whooping cough, which had been nine, five, and five in the three preceding weeks, rose again last week to 11 The 186 deaths in Dublin last week included 29 among children under one year of age and 50 among persons aged 60 years and upwards, the deaths of infants showed a considerable decline from the number in the preceding week while tho o of elderly persons decreased but slightly Three inquest cases and six deaths from violence were registered, and 75 or more than two fifths, of the deaths occurred in public institutions The causes of 10 or more than 5 per cent, of the deaths registered in Dublin last week were not certified

THE SERVICES

Royal Navy Medical Service

The following appointment is notified —Civil Practitioner J P Fall to be Surgeon and Agent (dated Jan 30th, 1904)

Royal Army Medical Corps

Major A. J Luther and Captain G A Moore on arrival in India are posted to the Bengal Command Colonel J J Morris joins the Southern District Major J Will is appointed Principal Medical Officer in the East African and Uganda Protectorates

Army Medical Reserve of Officers

Surgeon Major G H Darwin having resigned his Volunteer appointment ceases to belong to the Army Medical Reserve of Officers Surgeon Captain W P Peake having resigned his Volunteer appointment ceases to belong to the Army Medical Reserve of Officers

Volunteer Corps.

Rifle 4th Volunteer Battalion, the Norfolk Regiment Surgeon Captain W G Galletly resigns his commission (dated Feb 3rd, 1904) 1st Volunteer Battalion the Suffolk Regiment Surgeon Captain F Ward resigns his commission (dated Feb 3rd, 1904) 1st Lanarkshire Surgeon Lieutenant J G Andrew to be Surgeon Captain (dated Feb 3rd, 1904) 1st Volunteer Battalion the Royal Sussex Regiment Ernest Rivay Hunt to be Surgeon Lieutenant (dated Feb 3rd, 1904)

Royal Army Medical Corps (Volunteers)

The Aberdeen Company Lieutenant A H Lister to be Captain (dated Feb 3rd, 1904)

Volunteer Infantry Brigade Bearer Company

Sussex and Kent Captain O Jacomb Hood is appointed to command under paragraph 55A Volunteer Regulations (dated Feb 3rd, 1904)

The New Army Reorganisation Scheme

The three members of the War Office Reconstitution Committee have certainly lost no time in making up their minds on the matters submitted for their consideration and in expressing in clear and perspicuous terms the conclusions at which they have arrived Nor can it be said that the measures proposed by the Reconstitution Committee as outlined in its report are not of a sufficiently radical and comprehensive nature for they assuredly are and they are made, moreover, with the approval of the King The committee evidently set about its work in a thoroughly earnest and determined way from the standpoint that the British Empire is pre eminently a great naval Indian, and colonial power, and, so far as the War Office is concerned, with a single eye to adapting that institution to the needs of war The new scheme is a bold and comprehensive one It proposes the abolition of the office of Commander in Chief and the appointment of an Inspector-General to replace him, the creation of an army board on the model of the Board of Admiralty, together with sweeping changes at the War Office, to be carried out with the least practicable delay—because new measures demand new men That radical organic changes are called for and are to be regarded, indeed, as essential to any scheme of Imperial defence most people believe No final judgment of the scheme can be pronounced, however, until we know more of it in detail and of the proposed method of giving effect to it—for some knowledge of men, as well as of measures, is required The most capable men must be selected to fill the new official posts and to supply the places of any displaced and not simply those who happen to possess the greatest interest or high titular rank and distinction Meanwhile, it may be safely said that the new scheme promises well and has been favourably received. It remains to be seen how far and in what respects the Army Medical Services will be affected by the great and important changes proposed by the War Office Reconstitution Committee It is just possible that the ultimate result may be some attempt at the organisation of an Imperial Medical Service

Royal Army Medical Corps Examination

The undermentioned gentlemen were successful at the recent examination in London for commissions in the Royal Army Medical Corps 58 candidates entered

The Imperial Navy of Japan

Baron Saneyoshi F R C S Eng, chief of the Bureau of Medical Affairs in his report for the year 1901 states that the health of the Imperial Navy of Japan was generally very satisfactory The mean daily force in the service was 26 469 persons, which shows an increase of 3172 as compared with the preceding year The number of cases of disease and injury reported shows as a result of the expansion of the navy, an increase of 2237 cases when compared with 22 817 cases of the preceding year and the number of days sickness gives an increase of 48 750 days when contrasted with 536 115 of the previous year But the ratio of men sick daily and that of cases per 1000 of force show a decrease In the group of diseases of the urinary and generative systems there were 456 cases which give a ratio of 17 23 per 1000 of force, being an increase of 3 09 as compared with the previous year There was no case of death recorded Invalidings numbered four, giving a ratio of 0 15 per 1000 of force and being an increase of 0 02 as compared with the preceding year The total number of cases of venereal diseases was 5926 the ratio per 1000 of force being 223 88, which shows a decrease of 5 76 when compared with the previous year There was no case of death but there were 13 persons invalided from the service the ratio per 1000 of force being 0 49 which gives an increase of 0 02 over the preceding year Venereal diseases are most numerous of all the cases every year and they show a ratio of 23 75 per cent. of the total number of all the cases recorded. Arranged in order of number they are as follows: gonorrhœa and its sequelæ, 1918; soft chancre, 1587; bubo, 1316; secondary and tertiary syphilis, 800; and hard chancre, 305.

RECRUITING FOR THE ARMY.

The recent report of the Inspector-General of Recruiting was not altogether pleasant reading, as our readers are aware, for those who have the interest of the army at heart. Much stress was laid in that report upon the great importance of inquiring into the reasons for rejections of recruits on physical grounds in order to discover by what means the number of medical rejections can be lessened or obviated. The Inspector-General has since issued a memorandum to recruiting authorities which states that the question of physical degeneration, recently brought prominently forward, has drawn attention to the great difference in the numbers of medical rejections in the various recruiting centres, mainly attributable, it is believed, to the variety of systems employed. With the view of securing a fuller and more accurate system certain changes have been introduced. Quarterly returns are to be rendered in future from regimental districts embodying various new points of information. All recruiters are to be carefully instructed in carrying out preliminary examinations, so that the time of medical officers may not be wasted in examining men who are obviously ineligible.

"Audi alteram partem."

THE PROPOSAL TO PROHIBIT MEDICAL PRACTITIONERS FROM DISPENSING.

To the Editors of THE LANCET.

SIRS,—I have read with serious interest your leading article in THE LANCET of Jan. 23rd, p. 242, upon the suggestion to prohibit medical men dispensing their own medicines. At first I must confess to having felt somewhat staggered by the suggestion, but upon further consideration the difficulties associated with such an innovation rapidly disappeared from my mind and I have come to regard such a prohibition as salutary, necessary, and progressive. That it would raise the general tone of the profession there can be no doubt. Undoubtedly, also, it would rouse the energies of many a medical man and instead of their slipshod manner of practice—only, alas, too frequent—it will compel them to furbish their professional knowledge and to make readier and more careful use of the manifold methods of arriving at a diagnosis or be left behind in the ever-heated struggle for success. Before, however, so great a strain is thrown upon a hard-worked profession by such a prohibition [illegible] Parliament [illegible] bounden duty of Imperial [illegible] ciently the interests and welfare of our [illegible] be absolutely protected from the irr[illegible] of the "prescribing" druggist and [illegible] ruin to many medical men in the [illegible] vested the General Medical Council [illegible] Society must have full power to [illegible] practice, injurious alike to us and the [illegible]

There is much food for reflection [illegible] suggested prohibition. Consider, [illegible] a very usual type of general practice [illegible] patients and club patients. In any [illegible] safeguards suggest themselves: 1. [illegible] proved to have prescribed for any [illegible] fined and that for a second offence [illegible] his name [illegible] should be [illegible] by the Phar[illegible] Practitioner [illegible] friendly society [illegible] of mixture like a druggist. It is true that somewhat by the less frequent home consultation, but the we shall have no drug bill to meet at the end of the year. It may drive many more to the out-patient departments of our hospitals, but this will be met by keen competition among the dispensing chemists and the hospital authorities will be compelled to expel from such out-patient departments the many hundreds of "well to-do" poor who are quite able to [illegible] a half-crown or five-shilling fee to their medical man. To the general practitioner who does his own dispensing it will mean a gain of two hours daily for rest, recreation, or reading; to the man who keeps a dispenser it will mean a saving of the dispenser's salary.

I am confident that nothing but good will come of such a prohibition. We have got rid of the unqualified assistant, so much the better for our patients. If we can get rid of dispensing, so much the better for us. It will prove, I [illegible], a great stimulus to all kinds and classes of friendly societies, for women and children as well as men. The working classes will naturally seek refuge in [illegible] from the [illegible] expense of private medical treatment. It will make [illegible] tend to make them more provident, and so prove a universal good. Provident [illegible] will spring up all over the country and therefore the [illegible] and welfare of the medical men appointed thereto must be settled and legally assured in advance. What can be done in America, in France, and in Germany can be done here. The tone of general practice cannot [illegible] in the estimation of the poorer classes than at the present. These dispensaries and "open surgeries" have [illegible] It is time that an advance was made towards a higher grade of practice.

I am, Sirs, yours faithfully,
F. [illegible], M.D. Durh.

London, S.E., Jan. [illegible], 1904.

To the Editors of THE LANCET.

SIRS,—The settlement of this vexed question by the pro[illegible] legislation must, it seems to me, be [illegible] of its relation to our [illegible] medical efficiency. In France [illegible] dispense. We have [illegible] however, of the social position [illegible] tioner in his country [illegible] England it is distinctly [illegible] being greater it is decidedly [illegible] to help his patients being [illegible] lowered. The French medical [illegible] laws so constructed to [illegible] who qualifies in medicine and in pharmacy [illegible] the latter as a profession [illegible] have had with French [illegible] freer and more liberal [illegible] often are driven [illegible]

To the Editors of TH[illegible]

SIRS,—[illegible] comments on the non-[illegible] Medical Act Amendment Bill [illegible] as you say, show's [illegible] conditions of medical practice in country places. I wish the medico-political committee would understand that: 1. A medical man is a perfectly competent dispenser of his own prescriptions, and in country places, where some drug must at times be wanting, he is the best dispenser, for he can substitute another with no injury to the patient. 2 That there is nothing disgraceful in a medical man dispensing. There is nothing more *infra dig.* in mixing drugs than in administering an enema or washing a wounded hand in soap and water. If there is a perfectly trustworthy nurse at hand the medical man gladly leaves it to her, but in doing anything for the good of his patient the practitioner does not lose dignity. 3. That all medical men find dispensing irksome and that they readily and joyfully avoid it when circumstances permit. They can be trusted to decide when it is advisable to do so, being far better judges of local conditions than the General Medical Council can ever be.

The country practitioner has the highest interest in the efficacy of his drugs and can be trusted to keep these, his weapons, in the best working order. It is not to the interest of his patients that they should be compelled to go to the village druggist, who is often a man in a very small way of business, and one who ekes out a precarious living by selling wines, groceries, and the like, and also, it cannot be denied, by prescribing for all sorts of ailments. Suppose the village druggist goes in for early closing must the medical man also "close"? He is not much use without his armoury. How about branch surgeries? How far from the sacred village drug shop may the practitioner dare to dispense medicine without fear of being guilty of infamous conduct? Must he travel at least three miles so as to be a *bonâ-fide* traveller? Suppose the druggist does not, and will not, keep certain expensive drugs that the medical man uses, can the latter dare to buy and to dispense these? Suppose a druggist gets an injunction from the General Medical Council forbidding the medical man to dispense and then starts a store and fails, how long must the medical man deal with him? Until the last dose is sold or until he is bankrupt? Such a Bill would flood the country with young men trying to start small shops and I fear the public would suffer severely, for good and fresh drugs are very expensive. Who is to report to the General Medical Council that a medical man is dispensing where there is room for a druggist? Can any one; and will the poor practitioner have to fight the case? [illegible]

he

if

have any influence with and for whose family I have dispensed many bottles of medicine, that it is a deliberate attempt by an ignorant majority to limit the usefulness of the country practitioner, and that its effect in the country will be to drive the poor, who cannot afford a double fee, to the prescribing druggist; also that it will greatly increase the Poor-law expenses and will almost ruin many friendly societies. I should think the clause was drafted by a lawyer who was totally ignorant of medical work in the country and who thought that medical men's drugs could be distributed in the leisurely way that legal documents are produced. After your clearly expressed opinions and the excellent letter of Dr. James Oliver I do not think there is much danger of this absurd clause ever becoming law, but practitioners should be on their guard, for an almost equally objectionable clause was attached to the Vaccination Bill and only objected to after it was too late.

I am, Sirs, yours faithfully,

PAGANUS.

Jan. 25th, 1904.

To the Editors of THE LANCET.

SIRS,—Many of us must be grateful to you for your leading article on this subject calling attention to the Draft Medical Act Amendment Bill of the British Medical Association, which deserves the word "impracticable" you apply to it. To compel medical men to give up all dispensing after the centuries it has been a custom, at short notice or none, is going rather too far and too fast—even if the institution is "to raise the tone and status of the profession." Would it really add to the dignity of the profession? Much of our work—obstetrical, surgical, and medical—is of such a nature that those who practise it can never hope for an exalted position in the public estimation. Compared with the other professions—army and navy, Church and law—it must always be content with a humbler status. "No man can be a hero to his valet" and much less can a valet be hero to his employer. The personal service often required of medicine is of such familiar kind as to engender a feeling like contempt in the recipient and many patients will not have as medical attendant one whom they may meet in society; therefore, as everyone must see from the very nature of their work, medical men must be content to find their recompense in other ways than in pride of station and social dignity. As you remark, it would be impossible to carry on a practice in a poor neighbourhood if the practitioner was debarred from dispensing, and even in fair mixed practice it would be impossible to keep the poorer patients. A druggist might be arranged with to supply the medicines. The usual charge in such cases is 1*d* an ounce dose; three doses a day for a week would cost 1*s*. 9*d*., not to speak of pills, draughts, &c , that might be necessary. A good fee from poorer patients—mechanics, artisans, shop hands, and clerks—would be half-a-crown, and this after paying for the medicine would leave the medical man 9*d*. Is this a sufficient reward for a medical man's services? The patient it might [illegible], should

[illegible] s fee to

[illegible] t do so.

[illegible] dispensaries. As it is these institutions hardly pay the medical attendant anything when the cost of medicine, &c., is deducted as dispensed by himself They would simply be impossible if it were necessary to arrange with a druggist for medicines. Do the authors of this Bill really mean to stop all dispensary and club practice? all the artisan and shop assistant work at present done? Where, then, would these folk go in illness? The hospital would be their only resource and yet we are hearing on all hands of how the out patient departments are overcrowded and abused by those able to pay something for attendance. How urgently necessary it is that many should be sent to the general practitioner to relieve the finances and the overworked staff of the hospitals, but it would be impossible for him to attend them if he were prohibited from dispensing. How would this course allay the "accidents," &c., that are complained of through the repetitions of prescriptions or their being handed on to persons they were not intended for? You say truly that preventing medical men from dispensing would be throwing a good deal of their practice into the hands of the counter prescribing druggist. Is this to benefit the profession or the public? Again, there is a considerable amount of capital invested in surgery fittings, appliances, bottles, &c., by the members of the profession. Suppose even half the medical men on the Register dispense their own medicines and the average value of a surgery is £50, are they to be summarily deprived of this asset without compensation? Those thousands of surgery fittings, &c , would be thrown on the market at once, and would therefore be unsaleable, especially as they would be useless in this country. Is there any provision in the Bill to compensate the medical man? Ought it not in justice to be done by the British Medical Association who is advocating this Bill?

Looked at, then, from any point of view it would be bad policy to prevent medical men from dispensing. The poor would be deprived of medical assistance and would be driven to the hospital or to the guardians. The better-to-do classes would have to pay for such hospitals and for their own medical attendance a great deal more than they have at present. The medical practitioner would have his surgery fittings, &c , compulsorily confiscated without any fault of his own and without compensation and be deprived of all his poor patients. And to balance all this we are told that the tone and status of the profession would be improved. But would it? It is to be hoped that the backbone of the profession, the general practitioner, will duly consider the matter and, if he sees as I do, oppose it at every opportunity.

I am, Sirs, yours faithfully,

SURGERY.

Jan. 25th, 1904

To the Editors of THE LANCET.

SIRS,—As a country practitioner who has entered the autumn of life I venture to hope that we (country practitioners) may rely upon your assistance for protection against the proposed "Medical Act Amendment Bill" in reference to the dispensing of medicines. I commenced practice in a town of 4000 inhabitants about 35 years ago. There are five medical men in practice here, all of whom dispense their own medicines. The great bulk of the people cannot afford to pay a medical man's fee and at the same time a chemist's bill, as they would have to do under the new Act. The consequence would be that the great majority of the people would be either prescribed for by the chemists or use the prescription of a friend or fly to the different quack advertisements which abound in all our local papers and may even be found in the leading London "dailies."

When I came to this country there was far more prescribing done by the chemists than by the medical man, but by perseverance, hard work, and by charging very moderate fees this has considerably improved but will soon revert to the old order of things if the Act passes in its proposed form. To me, as an example, the subject is a very serious one, for I cannot retrench. As the practice is so widely scattered I am compelled to keep three horses and a coachman. I have also to pay £47 per annum for rent for the simple reason that I cannot get a suitable house, with stables, for less. I am able to pay my way as it is but cannot put anything by for my old age. I pay £47 10*s.* yearly premium for insurance on my own life and that of my wife, and this is all the provision I am able to make for my family. It seems clear to me if this new Act passes in its present form that I and thousands of other country practitioners will be simply ruined. Our work is hard and often very anxious in its nature and now our anxieties are added to by this harassing legislation. I fail to see what harm I do in dispensing my own medicines and I have the comfort of feeling that I get the best of drugs for my patients.

I am, Sirs, yours faithfully,
M.R.C.S., L.S.A.
Jan. 28th, 1904.

THE INQUEST ON WHITAKER WRIGHT.

To the Editors of THE LANCET.

SIRS,—If it be allowable to reopen discussion on this sad case I should like to say that I am not alone in thinking the evidence adduced at the inquest held by Mr. Coroner Troutbeck (as reported in the *Standard* and the *Globe* newspapers) singularly inconclusive and quite inadequate to justify such an assertion as that made by the coroner himself—namely, that it was "absolutely certain beyond all possibility of doubt that the deceased took his own life." So far as can be judged from the published reports at least five persons were present for some minutes preceding the death, one or two being medical men, yet failed to detect any but natural causes of the occurrence. Surely the length of time which had elapsed after the deceased's return from the lavatory, where, on the theory of suicide by poison, the fatal dose was probably taken, would be sufficient to allow of its impregnating the breath with the distinctive odour. Yet the acting house physician of King's College Hospital, who particularly investigated this possibility, says: "His breath smelt of spirits but there was no smell of poison at all." Four other persons similarly failed to detect any peculiarity in this respect.

The necropsy, regarding which Dr. Freyberger gave evidence, did not take place until 21 hours after the death, and this is a very important point. For although the odour of prussic acid is a valuable test up to 12 hours after death it is not reliable later. Some of the organs, especially the brain, emit a similar odour where there is no suspicion of poison; and certainly the evidence of one man, however eminent, is not sufficient to establish the possibility that the odour of prussic acid, which was markedly absent during several minutes prior to the death and for some hours afterwards (as we are left to infer), should become a "penetrating smell" given off by "every organ of the body" so long after as 21 hours. At any rate, the nose is not of itself an adequate witness. Yet the only other criteria afforded by Dr. Freyberger are the *bluish tint* of the body and the *fluidity* of the blood, which are neither separately nor together distinctive. The majority of the pathological signs adduced are consonant with death from syncope due to heart failure as the result of natural causes, especially as accelerated by mental shock. No mention was made by any witness of the peculiar "cry" uttered by the majority of victims to prussic acid, the deceased did not fall as if shot, nor does he appear to have been convulsed or to have had relaxation of the sphincters (as in more than 50 per cent. of cases). The corrosion of the mucous membrane, adduced as found chiefly at the back of the tongue and in the stomach, is difficult to explain in the absence of any sign of acute pain manifested during life. Cyanide of potassium has an alkaline reaction and is not markedly caustic. But it rapidly deliquesces on exposure, giving off fumes of prussic acid as soon as moistened, making it difficult to understand how it could have remained any time on the tongue without becoming noticeable by the bystanders. There is, moreover, no evidence of the vehicle in which it would be necessary to preserve it prior to its being used.

Whitaker Wright was singularly reticent as to any intention to commit suicide. In fact, supposing he did take his own life, he seems to have been at some pains to throw people off the scent. The revolver at full-cock, with ball cartridge in every chamber and none fired, may be ranked with the at first suspected tabloid; but it is remarkable that the revolver was not found by the first searcher (who appeared to ransack every pocket), but came so readily to the hand of the coroner's officer. It is surprising that the knife, which also was found, failed to be adduced as evidence of intention. Mining engineers and many rich men carry the former as a weapon of defence. It is not clear that the revolver had a special pocket made for it in Wright's case. But it is easy to understand that the habit which he had contracted in America would not readily be given up in England, where he became a far more tempting bait to the footpad and burglar.

That Whitaker Wright had had a fatty and dilated heart is a fact of prime importance and this was established (or confirmed) by the post-mortem examination. I incline to consider the judgment of the five persons who were present before death and who attributed it to natural causes as by no means upset by the further evidence submitted to the coroner. I have given evidence in many cases of various kinds before no less than five different coroners during the last 40 years, but I cannot recall a single case in which any of the five coroners was satisfied with nose-evidence or in which I expected him to be.

I am, Sirs, yours faithfully,
D. BIDDLE, M.R.C.S. Eng.
Kingston-on-Thames, Feb. 1st, 1904.

To the Editors of THE LANCET.

SIRS,—On Tuesday, Jan. 26th, I was called in to attend Whitaker Wright at the time of his death and I naturally expected to receive an intimation as to the time and place of the necropsy. On Wednesday at 1.45 P.M. as I had received no such information I telephoned to Mr. Troutbeck who referred me to Dr. Freyberger, adding that the necropsy was probably already completed or at any rate still in progress. I can quite understand that the demands on the coroner's time may be very great, but at the same time I cannot but feel that it is in the interest of the public as well as due to our profession that the courtesy should be extended to us of inviting the medical man present at the death scene to be present at the post mortem examination. I am, Sirs, yours faithfully,
OLIVER ATKEY.
King's College Hospital, Feb. 1st, 1904.

⁂ Mr. Atkey ought to have been present at the necropsy, of course.—ED. L.

THE SANATORIUM TREATMENT OF CONSUMPTION: ARE WE ON THE RIGHT TACK?

To the Editors of THE LANCET.

SIRS,—There are 67 institutions in the United Kingdom given over to the treatment of tuberculosis. Let us say for (exaggerated) argument's sake these could receive 12,000 cases—of course they could not or anything like it, but let us put it at that. There are architects, builders, expensive sites, ornate hospitals, highly paid secretaries, chapels, chaplains, and all the usual details of hospital construction and maintenance in the charitable financial foreshadowing of the near future. Meanwhile there are the downs unused, the roof garden is neglected, the cheap and useless (now) agricultural land is ignored, and the camp of huts on those downs is never considered. We want 100,000 huts and 100,000 roof gardens. We do not want beautiful buildings on expensive sites but moveable camps on land of no agricultural value. We are not seeking to stay a transient epidemic; we are striving to eradicate the most devastating scourge of the human race. I read the other day of a new hospital the chapel of which was to cost £20,000. But, Sirs, the chapel for these afflicted people should be where the

Sermon on the Mount was preached and in the full eye of the healing "wind of God." We are simply canonising expensive inefficiency by inaugurating fresh hospital buildings.—I am, Sirs, yours faithfully,

GEORGE H. R. DABBS, M.D. Aberd.

Austin Friars, E.C., Jan. 20th, 1904.

THE POINT OF PRIMARY GONORRHŒAL INFECTION IN THE FEMALE.

To the Editors of THE LANCET.

SIRS,—The letter on this subject by Dr. J. H. Arton, published in THE LANCET of Jan. 16th, p. 190, deals with a matter of great importance and one on which *misconception* is probably rife. Whether Dr. Arton is or is not correct in supposing that in the female the cervical canal is the usual seat of primary infection in gonorrhœa, this much is certain, that *vaginitis* of any severity is an altogether exceptional result of gonorrhœal infection in adult women and yet it is probable that most men engaged in private practice regard vaginitis as the specific criterion of gonorrhœa. Recent authorities, doubtless, inculcate other views. Herman,[1] for instance, writes: "The gonococcus is short lived and easily killed; hence it is only a passing guest in the vagina. It lingers longest in the urethra; probably in the glands of the floor of the canal near the meatus; next longest in the cervical canal. Hence you will find it in the vagina only when the disease is acute and pus abundant." Again, Muir and Ritchie in their "Manual of Bacteriology," second edition, 1899, state: "In the disease in the female gonococci are almost invariably present in the urethra, the situation affected next in frequency being the cervix uteri. They do not appear to infect the lining epithelium of the vagina of the adult unless some other abnormal condition be present, but they do so in the gonorrhœal vulvo-vaginitis of young subjects."

But while gynæcologists, bacteriologists, and those whose duty involves the regular examination of prostitutes have correct views of the disease I think there can be little doubt that a large proportion of general practitioners are still under the influence of the erroneous doctrine taught in the medical schools and reiterated in text-books until a quite recent date that vaginitis, often brief in duration and trifling in severity, is the principal characteristic of gonorrhœa in the female. And yet it is precisely in general practice that, as Dr. Artón indicates, so much might be done to prevent gonorrhœal infection and to lessen the disastrous consequences of the disease. The existence of latent gonorrhœa in the male has recently attracted much attention. No less attention should be given to the true nature of gonorrhœal infection in the female which in private practice is, in nine cases out of ten, a sequel of the said latent gonorrhœa in the male and is further, as Dr. Arton rightly insists, the major source of a *considerable number of the diseases peculiar to women.* Apart even from the much greater frequency of the disorder there seems considerable evidence in favour of the view that gonorrhœa is a greater scourge of the human race even than syphilis. I am, Sirs, yours faithfully,

Alderney, C.I., Jan. 25th, 1904. M. EDEN PAUL.

CARBON MONOXIDE POISONING BY THE INHALATION OF CIGARETTE SMOKE.

To the Editors of THE LANCET.

SIRS,—In papers read some years ago before the Bolton and District Medical Society and the Lancashire and Cheshire branch of the British Medical Association I drew attention to, and described, some work I had done on this subject at the suggestion of Mr. Gibson Dyson, Ph.D. It was shown that the presence of carbonic oxide gas could be demonstrated in tobacco smoke by several simple experiments and also analyses proved that smoke from cigarettes [illegible] that obtained from [illegible] is pointed out that [illegible] cigarette the most dangerous form in which tobacco could be enjoyed. Only by inhalation could the contained carbon monoxide come in contact with the blood; the resulting carboxyhæmoglobin owing to its great stability would give an ever-increasing load to be pumped through the body, whilst the heart, together with the rest of the tissues, was suffering from a [illegible] centres. It was also pointed out that the connexion of carbonic oxide with the evils attending the habitual inhala*tion of cigarette smoke hitherto had been overlooked* and it was further suggested that the enormous amount of damage inflicted by this vice on the younger members of the community constituted a national danger and that some means should be adopted to minimise or to put an end to it.

I am, Sirs, yours faithfully,

Bolton, Jan. 26th, 1904. J. HILTON THOMPSON, M.D. Vict.

THE MEDICAL DEFENCE UNION.

To the Editors of THE LANCET

SIRS,—In your able and instructive comment upon the action, Salisbury *v.* Gould, you made the statement that the Public Authorities Protection Act pleaded technically in addition to the evidence for the defence did not prevent Mr. Gould from being exposed to the anxiety and the expense entailed by an action persisted in until the jury refused to hear any more of it. It is quite true that the Public Authorities Protection Act did not so relieve Mr. Gould, *but the Medical Defence Union, of which association he was a member, clearly did.* To quote from a letter of Mr. Gould which I have before me in which he writes: "I was relieved not only of all trouble and anxiety but of very great expense, having only to go into the witness box and give my evidence. I cannot conceive how any registered medical practitioner can be so foolish as not to avail himself of the insurance afforded to all members of the Medical Defence Union." I am sure you will be willing to allow me to make this as an additional report to your article in your issue of Jan. 30th.

I am, Sirs, yours faithfully,

A. GEORGE BATEMAN,

General Secretary, Medical Defence Union.

Trafalgar-square, W.C., Jan. 29th, 1904.

⁂ We have much pleasure in publishing Dr. Bateman's letter. Mr. Gould, since the appearance of our article, has written to us in much the same terms of his gratitude to the Medical Defence Union.—ED. L.

TREATMENT OF DIABETES MELLITUS.

To the Editors of THE LANCET.

SIRS,—Will you kindly permit me to remark that I have read with much interest the clinical lecture on the treatment of diabetes mellitus by Dr R. T. Williamson in THE LANCET of Jan. 23rd, p 213. In the treatment of the disease with *drugs* Dr. Williamson gives the preference to salicylate of sodium and aspirin. I have not had much experience of aspirin, but I have been prescribing salicylate of sodium in diabetes for nearly 30 years and with so much satisfaction that I consider it my "official" remedy for the disease. I sometimes combine ergot with it, and I have the notes of cases written as far back as 1877 in which I found this combination most beneficial We have many remedies for diabetes but, unfortunately, no specific. We have few specific remedies for any disease, with the exception, perhaps, of arsenic for pemphigus, balsam of Peru for scabies, iodide of potassium for tertiary syphilis, quinine for ague, and bromide of potassium for epilepsy.

After all, the great difficulty in the treatment of diabetes is the dietary. Most of the articles of food in present use are so unsavoury that patients soon loathe them. A modification of the well-known "boxty" cake of the "Green Isle" might occasionally be given with impunity; it is rather appetising and I find that a meal or two is relished by most patients. The principal ingredient of it is fibrin procured from peeled, grated, raw potatoes from which for this special purpose the starch is abstracted and the fibrin only is retained. To this are added salt, eggs, some condiment, and sometimes a little flour. The mass is made into cakes and fried in a quantity of butter. I am sure that the readers of THE LANCET will mentally thank Dr. Williamson for his able lecture on that perplexing disease diabetes.

I am, Sirs, yours faithfully,

WILLIAM O'NEILL, M.D. Aberd., M.R.C.P. Lond.

Lincoln, Jan. 30th, 1904

MOSQUITOES AT SEA.

To the Editors of THE LANCET.

SIRS,—As mosquitoes have been found to be distributers of many serious diseases it may not be out of place to call attention to the frequent presence of these pests on sailing ships at sea and to suggest the possibility of their being responsible for the continuance of certain fevers on these vessels. Sailing ships leaving a tropical port always take away many mosquitoes which breed and keep a succession for weeks or even months. It is conceivable that, if a fever be epidemic at the port left, some of the mosquitoes carried away may belong to the variety capable of conveying that fever from one human subject to another.

There are many places on a sailing ship in which mosquitos may increase; stagnant rain water in boats, fire-buckets, and elsewhere, receptacles for keeping the day's issue of fresh water in cabins and forecastle which are often never completely emptied for weeks together and in which the larvæ can come to maturity. If salt water be added to the stagnant fresh water and tanks and buckets for the daily issue of fresh water be entirely emptied frequently or at least once a week mosquitoes soon disappear. This is, however, so simple a proceeding that it is often omitted and a constant succession of mosquitoes is kept up in some cases for the whole voyage. On steamships the conditions do not seem to favour the continuance of mosquitoes and I have never noticed them after the first day or two. I may add that I speak from an experience of 30 passages in sailing ships. I am, Sirs, yours faithfully,

Tavistock, Jan. 30th, 1904. F. O. SHAW, M.R.C.S. Eng.

THE INCIDENCE OF LEPROSY IN THE BRITISH EMPIRE.

To the Editors of THE LANCET.

SIRS,—With reference to the report on the incidence of leprosy, &c., in the British Empire, which I am preparing for the forthcoming International Congress of Dermatology at Berlin, I should feel obliged if you would kindly mention in your esteemed journal the lines on which it is proposed the data should be collected, viz.:—

1. *Statistics*.—(*a*) According to official reports (Government); and (*b*) leper asylums, settlements, missions. Details as to these—race, sex, and age of inmates. Type of disease.

2. *Methods employed to cope with leprosy between 1897 and 1903 (inclusive)*.—(*a*) Government laws as to leprosy; and (*b*) means taken by governments, municipalities, parishes, private societies, &c., for the suppression of leprosy: (1) number of leper asylums, hospitals, and settlements; (2) number of beds, &c.; (3) fluctuations in the number of lepers, &c.; (4) occupation of lepers in institutions, settlements, &c.; and (5) transport by rail, steamer, ambulance, &c.

3. *Lepers in general hospitals, infirmaries, lunatic asylums, prisons, &c.*

As the request for the treatment of the subject on the above lines only came to hand after I had got out my circular letter to our numerous colonies and protectorates, it would help me very much if I could have the valuable assistance of publicity in your columns.

I am, Sirs, yours faithfully,

GEORGE PERNET,
Assistant to the Skin Department, University College Hospital, &c.
Upper Gloucester-place, N.W., Jan. 31st, 1904.

MALIGNANT GROWTHS AND NORMAL REPRODUCTIVE TISSUES.

To the Editors of THE LANCET.

SIRS,—The theory of spermatic influence has long been discarded as an explanation of the origin of carcinomatous processes. Professor J. B. Farmer, Mr. J. E. S. Moore, and Mr. C. E. Walker have expressed their opinion that the malignancy of cancer is due to tissues which have undergone a reducing division and have demonstrated that heterotypic and homotypic mitoses occur in the deeper layers of carcinomata and sarcomata. This has been confirmed by Dr. E. F. Bashford and Dr. J. A. Murray in malignant tumours from the trout, the mouse, and the dog. The interpretation of these "intrinsic" changes remains to be decided, but in general terms it seems to point as before to the determination of which of the "extrinsic" factors of cell growth varies from the normal, as compared with the "intrinsic." A fuller explanation of the phenomena of cell growth from the period of fertilisation of the ovum to the adult stage, of acromegaly, of the potentialities for secretion of glands, such as the testis, ovary, &c., cannot fail to throw light on the origin and nature of the disease. It is to be hoped that the Cancer Research Fund, the British Medical Association, and other bodies will assist those medical men who reside in the provinces to carry out both general and cytological investigations when opportunities arise and the workers are to be found.—I am, Sirs, yours faithfully,

F. BUSHNELL, M.D. Lond.,
Honorary Pathologist in charge of the Clinical Laboratory,
South Devon and East Cornwall Hospital,
Plymouth.
Plymouth, Jan. 30th, 1904.

ROYAL MASONIC INSTITUTION FOR BOYS.

To the Editors of THE LANCET.

SIRS,—Would you be kind enough to insert the inclosed appeal in an early number of THE LANCET? This boy is the only candidate at the April, 1904, election who is the son of a medical man and so ought to have the sympathy of all medical Freemasons.

I am, Sirs, yours faithfully,

Bewdley, Jan. 27th, 1904. U. W. N. MILES.

⁂ The case referred to by our correspondent is that of Patrick Trevor Webster, whose father, the late Mr. Trevor Webster, a member of the Lechmere Volunteer Lodge, No. 1874, practised at Bewdley, and died on Oct. 28th, 1902, leaving a widow and seven children very inadequately provided for.—ED. L.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

A Sanitary Association for Bombay City.—Technical Scholarships for Bengal.—The Plague Epidemic.

AN attempt is being made in Bombay city to excite an interest in the general study of sanitation and the Governor presided recently at a meeting for the purpose of establishing a sanitary association. A number of objects are specified as being aimed at in connexion with the association, three of them being: (1) to create an educated public opinion with regard to sanitary matters in general; (2) to provide its members with such advice as shall insure a proper sanitary condition of their dwellings and enable them to procure practical advice as to the best means of remedying defects in the houses of the poorer classes in which they are interested; and (3) to deliver lectures in English and the vernaculars to all people (males and females) of different castes and creeds. This is a very comprehensive programme and is, I believe, due to the initiative of Dr. J. A. Turner.

Another educational movement is being provided for Bengal in the shape of State technical scholarships. The subjects of study are law, medicine, forestry, veterinary science, agriculture, and engineering. The scholarships will be of the value of £150 a year and tenable for two years. They may be held in Great Britain, the continent of Europe, or in America. Natives of India only will benefit. No age limit is fixed. The idea is to provide higher technical education for promising natives of India in order to promote the improvement of existing native industries and, if possible, to develop new ones. As medicine and veterinary science are included it will give opportunities to deserving students to enlarge their knowledge and ideas upon these subjects in the advanced countries. The value of this scheme cannot be questioned and may be placed next to the establishment of industrial institutes and experimental research laboratories among the new institutions arising in India.

The plague mortality, as expected, is resuming the increase which has been in progress during the past few months.

For the week ending Jan 9th there were 17 344 deaths from plague throughout India as compared with 16,503 for the previous seven days and with 16 197 for the corresponding week in 1903 The disease is evidently developing again in Bombay city and continues in Poona There are now so many more centres for plague that the recrudescence which is making itself felt all over India may be expected to assume very large proportions. The monthly statement published showing the incidence of plague in the Bombay Presidency reveals the fact that the excess mortality in the various towns and districts is not covered by the returns of plague The obvious inference is that there is a greater mortality from plague than the returns indicate I have had occasion to point this out for years past as the figures for Bombay city, Karachi, and Poona tell their own tale In the districts this anomaly is not surprising, but in the large cities more accurate estimates should be forthcoming Calcutta seems to be the only place in which a fairly approximate estimate is made of the amount of plague, the figures for each year showing that the whole of the excess mortality has been due to this disease

Jan th

THE RUSSIAN MEDICAL CONGRESS DISSOLVED BY THE POLICE

(FROM OUR SPECIAL CORRESPONDENT)

THE Russian Medical Congress which met at St Petersburg at the end of January has been dissolved by the police In Western Europe it will seem extraordinary that a technical and scientific congress cannot be held without police interference On the other hand, it is easy to see how in Russia such things may happen The practice of medicine there is not independent of politics and when questions of sanitation or of the prevention of disease are approached science is at once forced into the political arena Even in England vaccination and vivisection are sometimes made test questions during the heckling of Parliamentary candidates In Russia the position is far more serious Medicine and sanitation can certainly divorce themselves from party politics such as we know them in England, but medical men and men of science generally would be compelled, not only as individuals but in the name and for the defence of their profession, to take part in politics if they were denied the freedom necessary for the pursuit of their studies This is precisely what is happening in Russia. At the St Petersburg congress a joint meeting was held of the sections on tuberculosis and on social hygiene Here a motion was carried setting forth that the ignorance of the ordinary and elementary laws of hygiene and the excessive drinking of alcohol created the predisposing causes that facilitated the spread of tuberculosis which is one of the most fatal of prevailing diseases So far so good, but the motion and the speeches by which it was supported went a step further, for a clause was ultimately adopted to the effect that a regular and systematic campaign against tuberculosis could only be carried out in Russia on condition that "personal freedom and the freedom of speech, of the press, and of meeting were granted' In the existing circumstances and considering that Russia is an autocracy, it would seem as if the medical profession had here outstepped the bounds of prudence and was asking for what it knew perfectly well would not be granted and for what was not necessary for its purpose Consequently the adoption of such a motion might be construed as an act of aggression against the Government and therefore justified the dissolution of the congress The resolution practically asks for complete freedom and this is not necessary when it is simply a question of teaching the ignorant masses the advantages of cleanliness, of thorough ventilation, and of abstinence from excessive drinking Unfortunately these arguments, however plausible from the point of view taken by the present autocratic Government do not in practice cover the issue Such freedom as that suggested does exist It is possible to deliver lectures on ventilation or on the best means of keeping dwellings clean, but whenever any systematic effort of this sort is made the organisers immediately fall under the suspicion of the police These benevolent and charitable endeavours are ascribed to some political motive and a scientific lecture on sanitation may land its author in Siberia.

Worse than this, however, was to follow The medical men had not only the audacity to demand that their freedom to teach the laws of health should be absolutely guaranteed, but they actually touched upon the burning question of the treatment of the Jews The medical profession is called upon to bring its science to bear so as to reduce the prevalence of tuberculosis, and it answers, in no uncertain or faltering voice, that overcrowding and poverty are the principal culture beds of Koch's bacillus But the Russian Government by its anti Semitic enactments has increased to an enormous extent the overcrowding of the ghettos and the poverty that prevails therein There are supposed to be rather more than 5 000,000 Jews in Russia who, with but a few exceptions, are confined in certain portions of the towns within only a part of the empire By the "Laws of May," which the Emperor Alexander III signed on May 3rd, 1892, the Jews were no longer allowed to reside in villages but only in towns or burgs The police were apparently left to decide whether a place was a village or a burg If they chose to call it a village then the Jews might be driven out in 24 hours Thus, for instance in 1895 all the burgs of the provinces of Poltava and Tchernigoff were declared to be villages and the Jews had to leave in 24 hours The results of this unnecessary haste are appalling The Jews have to sell their property at a ruinous sacrifice and thus poverty is added to the overcrowding of the ghettos in which they are compelled to live Another illustration may be given of the way in which this political action against the Jews affects the public health and must be taken into consideration however anxious we may be to avoid any allusion whatsoever to politics The vice governor of Kishineff some time ago gave orders for the evacuation of a burg which was henceforth to be qualified as a village The subordinate who lived on the spot immediately requested that this rigorous measure might be deferred as a severe epidemic of small pox prevailed at that time This very natural protest was however, unavailing The Jews were all forced out of their houses and whether ill or in good health they were crowded together into carts and driven into Kishineff It was mid winter Many of the children died on the road and the epidemic of small pox was introduced into the town of Kishineff The question with regard to the Jews may be a political matter but it has also a very serious effect on the public health It is estimated that since the "Laws of May" more than 600,000 Jews have been driven out of places now called villages and compelled to increase the overcrowding of the ghettos of the towns

Is it surprising if, in the face of such facts, the Russian Medical Congress should adopt a motion "calling attention to the danger resulting from the artificial concentration of the Jewish population in the authorised zone of residence established for the Jews in the towns and burgs of the south and west of Russia"?

Then there are laws which forbid the Jews to bathe in lakes or rivers, nor are they allowed to go to seaside watering places, to sanatoriums, or to mineral wells The congress therefore passed a motion demanding that patients, even if they are Jews should be allowed to seek the benefit of the country air and "be permitted to inhabit the country or to follow a cure at a sanatorium or a watering place, and the congress considers that it is indispensable to grant the Jews the right to go from place to place"

At present a Jew may not live in the more healthy or suburban parts of his town but must inhabit the ghetto However ill he may be and though his life might be saved by a change of air still he must remain in his ghetto If he desires to seek the advice of a medical practitioner who lives in some other town he cannot do so unless he first obtains a special authorisation from the police In such circumstances it is not surprising that the death rates in these towns are high and that epidemic diseases have become endemic in many of the ghettos Yet when the medical practitioners of Russia are in congress assembled and very naturally protest disease they are accused of congress is dissolved by the if this is not followed by the arrest and imprisonment of some of the more earnest speakers But how medical science and sanitation can progress under such conditions is a question which the Russian Government must be left to answer

TRIPLE COMPULSORY VACCINATION IN FRANCE.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

No. II.[1]

IT being now enacted by law that everyone who lives in France, whether a French subject or a foreigner, shall be vaccinated three times, that is, during the first, eleventh, and twenty-first year, the next question is to indicate how this law is to be put into practice. On this subject a special decree was issued on July 27th, 1903, signed by the President of the Republic, M. Emile Loubet, countersigned by the Minister of the Interior and the Minister of Justice, and published in the *Official Journal* of July 31st. After quoting Article 6 of the new Public Health Act of Feb. 15th, 1902, the decree explains that, according to the stipulations of this Act, the Academy of Medicine and the Consultative Committee of Public Hygiene have been duly consulted and, in harmony with the opinions of the Minister of Justice and the Council of State, the following regulations are issued. It is first explained that the vaccination service established at the Academy of Medicine is intrusted with the duty of providing the best vaccine lymph. It is further instructed to endeavour to improve the production of vaccine lymph and the methods of vaccination. Thus the law goes out of its way to urge that there is always room for improvement. Finally, this service, established by the Academy of Medicine, must make all the scientific experiments and tests necessary to control the establishments which prepare and distribute vaccine lymph. This means presumably that there shall be one standard of excellence—that set up by the most competent authority on the subject—and this standard is to be enforced throughout the country. Every year the Academy of Medicine must report to the Government the results of the vaccination and revaccination practised, especially in regard to towns where there are more than 20,000 inhabitants. The decree then goes on to say that no one shall be allowed to open an establishment for the production and distribution of vaccine lymph without first notifying the prefect of his district and placing himself under full public surveillance and control.

Article 4 of the decree stipulates that in each commune there shall be séances for gratuitous vaccination and for the revision of the results. Public advertisements shall announce when and where these vaccination séances will be held and shall recall the obligation imposed by the law on all persons in this matter. All parents or guardians must take the children in their care to be vaccinated or produce a certificate proving that this has already been done. The prefect, however, is authorised (Article 5) to stop the vaccination of the population while some other epidemic than that of small-pox prevails in the neighbourhood. The municipalities must draw up lists (Article 6) first of all children more than three months and less than a year old on the day they were vaccinated and who were born in the commune. This list must be compared with the registrar's returns. Secondly, there must be a list of children of the same age living in the commune but born in another locality. Thirdly, there must be a list of children who have exceeded the age of one year but who for some reason or other have not been vaccinated. Fourthly, those who have been vaccinated but who must be vaccinated again because the operation did not succeed must be recorded. It will be seen that the second list mentioned above comprises the children of English and other foreign families residing in France.

In regard to the first revaccination the directors of all public or private schools must report all pupils who are in their eleventh year, so that they may be revaccinated. Also, they must report any child, no matter of what age, who happens not to have been vaccinated. Thus if English parents send their children to any school in France and these children have not been vaccinated the fact will be reported and they will be vaccinated forthwith. If these children have, however, been vaccinated in their infancy they will be again vaccinated when they reach their eleventh year or if they have passed their eleventh year and have not been revaccinated. Where a child is not sent to school but is kept at home with the parents or guardians the latter are held legally responsible for the inscription of that child on the lists drawn up by the municipality giving the vaccination statistics. In regard to the second revaccination the list comprises all persons who happen to be residing in the commune and who have reached their twenty-first year. Then there are some details given as to how the records are to be kept and Article 8 authorises the vaccinator to postpone the operation if the subject is not in a suitable state of health. Where the vaccination does not succeed it should be repeated as soon as possible. A medical certificate stating that the law has been duly observed can only be given when there is no result after three attempts have been made. It is the duty of the mayor of each commune to send a notice to all persons who have failed to conform to the above stipulation warning them that if before the expiration of the year during which they should be vaccinated they do not produce a medical certificate showing that this operation has been successfully performed proceedings will be taken against them. Should this warning prove of no avail the matter is to be handed over to the police and the Minister of the Interior and the Minister of Justice will, each according to his respective function, see that the law is enforced.

This decree was followed by a Ministerial circular, dated August 7th, 1903, and addressed to all the prefects. It gives explanations elaborating the various clauses of the law. Thus the prefects are reminded that while in many countries vaccination was enforced and its utility proved beyond the possibility of doubt small-pox continued to make many victims in France because vaccination could not be applied to everyone. The object of the law, therefore, was to produce in France results as favourable as those that have been attained in other countries. The prefect is to appoint the medical men and other agents necessary for the organisation in each locality of a public vaccination service. The *conseil général* or county council will have to decide where and how frequently gratuitous vaccination shall be offered to the populations in the various districts and what remuneration shall be given to the medical men who do this work. But the appointment of the public vaccinators is not left to the local elected body or county council. It is the representative of the Central Government, the prefect, who appoints and he makes his selection acting under the instructions in regard to technical and professional competence elaborately prepared by the Academy of Medicine and the Consultative Committee of Public Hygiene.

The circular then explains that in rendering vaccination obligatory the law does not seek to make vaccination depend exclusively on the public authority. It is only where individual initiative and the normal participation of the medical corps in the practice of vaccination and revaccination fail that the administration has the duty of periodically providing the necessary facilities. Everyone is free to select the medical practitioner whom he prefers and the time that suits best so long as he produces the certificate proving that the vaccination has been properly done. On the other hand, there must be at least once in the year free vaccination offered in each locality. Where, however, two localities are close to each other and have but few inhabitants the vaccination séances may be held alternately in the one or the other locality. Where small-pox is actually prevailing supplementary gratuitous vaccination must at once be organised, indeed the circular recommends house-to-house vaccination so that the disease may at once be stamped out before it has time to spread extensively. Then the circular points out that though the lists which the mayors must draw up will serve as the basis for action in applying the law, the fact that the name of a person happens to have been omitted from such a list does not exempt him from the obligation of conforming to the law. Also, the circular explains that though the law does not insist on revaccination after the twenty-first year the public vaccinators should always be willing to vaccinate anyone and at no matter what age. If there are cases of small-pox it is especially advisable to encourage revaccination at all ages and therefore the entire population should be urged to avail themselves of the opportunities offered.

From this it will be seen that permanent public vaccinators are not to be appointed as in England. Perhaps in rural districts and in very small towns this may not be necessary, but in large centres there will be work enough to be done all the year round to keep vaccination offices open permanently. This doubtless will follow in due course when its necessity makes itself felt. In the meanwhile the French legislature may be congratulated on having fairly taken the bull by the horns. In the course of a year or two the vital statistics will, in relation to small-pox, establish and vindicate the wisdom of this proceeding.

---

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool Royal Infirmary; the New President; Handsome Donation.

THE annual meeting of the trustees of this infirmary took place on Jan. 20th. The treasurer in his remarks made allusion to the endowment of three beds during the year in memory of friends or relatives—by Sir Thomas Brocklebank, in memory of his daughter; by Mrs. Hamilton B. Gilmour, in memory of her husband who had been chairman of the committee for a period of 19 years; and by the President, Mr. James Lister, in memory of his grandfather. The committee ardently hoped that at least 20 beds might be endowed. There had been received from the Hospital Saturday and Sunday Funds £3097. Legacies realised £2776, subscriptions accounted for £3665, whilst other donations added £1095 to the general fund. The total expenditure had been £15,045, to balance which £2649 had been transferred from the maintenance fund. The debt now stood at £2806. The average number of in-patients had been 253. 3307 patients had been admitted to the house. 323 patients died during the year. The number of out-patients treated was 19,205, whilst the total attendances reached 74,354. Mr. James Lister on retiring from the presidency presented the institution with 100 guineas. Mr. Edward Robert Bickersteth, the senior honorary surgeon, was elected the president for the ensuing year. Mr. Bickersteth, in expressing his sincere thanks for the great honour conferred upon him, said that he had been connected with the institution probably longer than anyone present. When he first became a student at the infirmary in 1846 things were very different from what they were now and nothing had been more interesting than to watch during his long career the rapid advance of kindness and charity. In 1856 he was elected honorary surgeon and occupied that position for 32 years. In his early days the hospital was devoid of mattresses and patients had to sleep on sacks stuffed with straw by the more able-bodied patients. There was a feeling at the time that if the patients were too kindly treated they would be more anxious than ever to gain admission. He had some difficulty in persuading the committee to accept 12 mattresses from him and they only did so on the condition that he would keep them in repair and replace them when necessary. In those days also there were no trained nurses and only one night nurse. How different things were to-day: he believed they now had the most perfect arrangements and every appliance that could be thought of. In conclusion he said he would be glad to present £1000 to endow a bed in memory of his father who was for 42 years a surgeon to the institution.

David Lewis Northern Hospital.

The chairman, in moving the adoption of the report and accounts at the meeting of the subscribers to this hospital on Jan. 20th, referred to the great urgency there was for increased support. They had only received £675 in legacies, as against £4000 in the previous year. The increase in the number of in-patients showed that there was a great need for additional funds; in fact, £1800 more a year were required to keep the institution in an efficient condition. The number of in-patients had increased to 2326. The number of out-patients had been 12,689. The ordinary expenditure had been £10,831. There was a debit balance of £5069, being an increase of £1377 over that of last year. The amount of the grant of the Hospital Saturday and Sunday Funds was £1865. The expenditure had exceeded the income by £1877 19*s*. 7*d*.

Conference at the Town Hall on Hospital Rating.

A conference was held at the town hall on Jan. 25th with [illegible] the payment [illegible] attendance [illegible] of the city, together with representatives of the Hospital Saturday and Sunday Funds. The following motions, brought forward by the Lord Mayor and seconded by Mr. H. H. Hornby (the representative of the Eye and Ear Infirmary), were carried:—

> T[illegible] ded to the rates by the [illegible] to the care and treat- [illegible] by voluntary contribu- [illegible] pectfully asked [illegible] to pass a Bill [illegible] in the manner [illegible] the House of [illegible] Government to introduce a Bill for this purpose during the ensuing session of Parliament.
>
> That a copy of this resolution be sent to each of the Members of Parliament for the city.

The hospitals are doing work that would otherwise rest as an obligation upon the city. Private philanthropy, by raising up so many institutions as exist in this city for the help of the sick and injured, relieves the ratepayers of Liverpool from a heavy burden which would otherwise have fallen on them, therefore exemption from the payment of local rates is not an unreasonable demand made by the managers of these useful charities.

Infirmary for Children: Annual Meeting.

At the annual meeting of the subscribers to the Liverpool Infirmary for Children, held on Jan. 27th, it was stated that the work of the institution was being seriously crippled owing to the pulling down, for sanitary reasons, of the infirmary building in Myrtle-street and the inadequacy of the temporary premises in Catherine-street. Dr. E. W. Hope (the medical officer of health) had reported favourably on the old site, trial holes had been sunk in parts of the site, and in addition the trial holes had been extended by a trench to the depth of ten feet. The sand and sandstone below the foundations were found in a virgin condition, clean and pure, and there were no evidences of percolation of any organic material. Rebuilding, however, could not be started until the amount already received (£20,000) had been increased by £10,000 more The total cost of the complete building is estimated at £60,000.

Preservatives in Marmalade.

At the Liverpool police-court on Jan. 27th a local grocer was summoned for having sold to Inspector Collins marmalade which upon analysis was found to contain five and a half grains of salicylic acid per pound. The prosecution held that it was quite unnecessary to add salicylic acid to marmalade. The defence urged that the acid was not injurious to health and that it was now used by many manufacturers. It was stated that the large quantity of acid used was unintentional. The marmalade in question was manufactured 12 months ago and it was thought that the employé who had made it had put in a *double quantity by mistake.* Mr. W. J. Stewart, the stipendiary magistrate, said there was not the slightest reason for putting any preservative in marmalade, especially salicylic acid. They were familiar with home-made marmalade which would keep for years if kept in the proper place. It seemed to him there was no object to be gained by putting the salicylic acid in the marmalade and whatever might be said that people were getting to understand the fact that salicylic acid exerted a beneficial effect on bacteria it might produce a prejudicial effect on the human organs. Perhaps they might put on the bottle or jar a notice that the marmalade contained some preservative and then purchasers would know they were taking in anti-rheumatic physic and marmalade together. It would be like taking powders in the old days—sealed in jams—and taking them without knowing it. He imposed a fine of £5 and costs.

City Coroner's Report for 1903.

The total number of cases of deaths reported to the city coroner during 1903 was 1784, compared with 1792 in 1902. Of these, 997 formed the subject of coroner's inquests as against 977 the previous year. The cases in which a verdict of murder was returned were three, the same as in the previous year. 59 cases of suicide were investigated, compared with 55 in the previous year. Want and exposure caused six deaths, as against seven in 1902. Alcoholic excess contributed 166 deaths, as against 165 in 1902. Want of proper attention at birth caused the deaths of 17 infants, as against seven in 1902. Accidents accounted for 476 deaths, compared with 523 in 1902. There were 41 drowning cases, as against 29 in 1902. There were 78 cases of burning, of which in 72 cases lack of fireguards or the use of *flannelette* was either the immediate cause or largely contributory, the deceased persons being young children or aged and infirm people. There were 84 cases of suffocation, as against 116 in 1902. The coroner remarked in regard to cases of overlying that in most instances the mothers had not removed the breast from the child's mouth before going to sleep. The majority of cases were free from suspicious circumstances. Suffocation cases of this kind were not altogether confined to persons in the lower grades of life. The fact that so many of these cases occurred late on Saturday or early on Sunday appeared to be accounted for, in many instances, by the presumption of the mothers being fatigued after an arduous day's work.

Liverpool Medical Institution: President's Badge of Office.

At the meeting of the Medical Institution held on Jan. 21st a badge of office for the president was presented. Sir William Banks, in a few appropriate remarks, made the presentation to Dr. James Barr (the new president) on behalf of the subscribers. Dr. Nathan Raw (who acted as secretary to the badge committee) endorsed Sir William Banks's remarks, at the same time wishing the President a happy and successful term of office. Dr. Barr suitably acknowledged the insignia of office. The badge is of gold, with blue enamelling, displaying on the front the Greek motto of the society and on the reverse the inscription, "President of the Liverpool Medical Institution, 1904."

New Horse Disease: Warning to Liverpool.

A letter was read at the meeting of the health committee of the city council on Jan. 28th from the Board of Agriculture and Fisheries drawing attention to the appearance among horses in England and Ireland of a new disease, called epizootic lymphangitis, which was stated to be very contagious. The symptoms were a swelling and eruption of the legs, generally the hind legs, and isolation was recommended. The veterinary superintendent of the health committee said that the disease had existed for some time in India and was carried during the late war to South Africa, and was subsequently transferred to this country. It had been discovered at several of the military depôts.

Feb. 2nd.

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS.)

Cardiff Medical Society.

THE annual meeting of the Cardiff Medical Society was held on Jan. 29th when Sir William Macewen, F.R S., LL.D., delivered an interesting and exhaustive address, taking as his subject the Diagnosis and Treatment of Appendicitis. At the annual dinner of the society which was subsequently held Sir William Macewen urged the establishment of a completely equipped medical school in Cardiff. The medical society, which has a membership of over 100, was formed in 1870, with Dr. Alfred Sheen as the first secretary. Of the other original members there are probably only two left in Cardiff—namely, Dr. W. T. Edwards, who was president in 1871 and in several subsequent years, and Mr. John Evans. In 1888 a medical library was established and the members of the society have now a very good collection of books in their rooms in Queen-street.

Swansea Workhouse Infirmary.

The new buildings which have been recently erected in connexion with the Swansea workhouse will facilitate the administration of the institution very considerably. They include an infirmary with wards to accommodate 71 patients, surgeons' rooms, nurses' rooms, and a lying-in ward. There are also women's receiving wards, vagrants' wards, a porter's lodge, and a disinfecting block. The infirmary is lighted with electricity and is heated with hot-water pipes, the floors are of wood blocks, and the walls have glazed bricks to the height of five feet. The buildings are constructed of stone and the entire cost was £17,730.

Colliery Work as a Board School Subject.

At many of the eisteddfodau held in the colliery districts of South Wales the contests are not confined to singing Prizes are given to the winners in ambulance and first-aid competitions and to those who are the most familiar with the Home Office rules regulating the collier's conduct when engaged at his work. These latter competitions must be of great value for neglect of the rules may have very disastrous results. It is gratifying to learn, therefore, that the education authority for the county of Glamorgan has decided that in future in the boys' schools under its charge instruction shall be given in subjects relating to colliery work such as coal-mine gases and how they become dangerous; the safety lamp and how to use it; the method of ventilating a colliery; coal and how it is formed; the method by which coal is worked in a mine; and the rules framed for a collier's safety.

Death of Mr. Jenkin Jenkins, L.R.C.P. Edin., L.F.P.S. Glasg, L.S.A.

Mr. Jenkin Jenkins, who died from pulmonary consumption at Aberystwith on Jan. 27th, had practised for more than 20 years in Pontypridd, where he was much esteemed. He was surgeon to several collieries, medical officer and public vaccinator to the town district of the Pontypridd union, and medical officer to the post-office.

High Death-rate in Merthyr.

In spite of the activity displayed during the past few years by the health committee of the Merthyr urban district council the town has still an unenviable notoriety with regard to the number of deaths recorded. For the week ending Jan. 23rd the death-rate from all causes was equal to 39·4 per 1000 per annum, the next highest rate among the 76 large towns being 29·5 per 1000 at Preston. For the five weeks ending Jan. 25th the Merthyr death-rate was equal to 32 5 per 1000 and of the 229 deaths registered during that period 119 were of children under the age of five years.

Royal United Hospital, Bath.

The annual meeting of the subscribers of the Royal United Hospital, Bath, was held on Jan. 27th, at the Guildhall, Bath. The medical report stated that 1397 in-patients had been admitted during 1903 against 1389 in 1902. The out-patients numbered 8632 compared with 7891 in the previous year, and 232 patients were visited at their homes against 349 in 1902. The average daily number of in-patients was 82. The financial statement showed that although the unfavourable balance of £4000 had not been reduced, at the close of 1903 the committee had increased its invested capital, by legacies, to the amount of £1434 The Rev. E. Handley, who for the past 13 years had been president of the institution, having resigned through ill-health, Mr. Richard Sumner Fowler, F.R.C S. Edin., who for a long period had been a member of the honorary staff of the hospital, was elected to the post.

Bristol Medical Dramatic Club.

The annual performances of the Bristol Medical Dramatic Club will be given at All Saints' Hall, Clifton, on Feb 9th and four following days, when *The Lancers*, by Captain Leicester Vernon, M P., will be presented. The proceeds will be devoted to the funds of the Bristol Royal Infirmary and the General Hospital.

Feb. 2nd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Retirement of Dr. D. Argyll Robertson.

THE Edinburgh Cap and Gown Club on Jan. 30th entertained Dr. D. Argyll Robertson at dinner to mark the occasion of his retirement from practice in Edinburgh Dr. Argyll Robertson announced some time ago his intention to retire from practice and to spend his closing years in Jersey. Mr. G. W. Barclay, F.R S. Edin., presided over a considerable company of the medical and other professions. In proposing the health of Dr. Argyll Robertson Mr. Barclay said that it was many years since, after taking his degree and studying abroad, the guest of the club began his life-work in Edinburgh. While practising physiology under Hughes Bennett he had already begun the study of the eye, with which his name was so particularly associated. He had held many highly important positions and numerous presidential appointments, among others that of the Royal College of Surgeons of Edinburgh, and at that moment he was surgeon oculist to the King in Scotland. The members of the club did not think that they could allow so old and distinguished a member to go from among them without holding out to him the hand of fellowship and wishing him every joy and happiness in his new home. Dr. Argyll Robertson, in responding, said that he wished he had had the power to give expression to the fulness of a heart that was overflowing with gratitude for the kind words that they had listened to and responded to. He assured them that it was with feelings of no small regret that he made up his mind to leave the city of his birth, the city in which he had contracted and formed so many ties of kindly friendship and of intimate good fellowship. Were it not for the circumstance that he felt an overwhelming desire for a country life, that he desired to be free from the cares and turmoils of practice and responsibility of office, he assured them it would be with extreme difficulty, if at all, that he could tear himself away from the most lovely city in the world. But in the sunshine of Jersey he would possess freedom from care and worry and the pursuit of golf and gardening and other recreations would be possible. He thought it was infinitely wiser to retire while yet perhaps a few years remained in which fairly good health and strength might be given to him and while his faculties were not altogether weakened and decayed.

Glasgow Royal Infirmary.

A public meeting, the object of which was to promote the scheme for the reconstruction of the Royal Infirmary, was held in the City Chambers, Glasgow, on Jan. 29th, the Lord Provost, Sir John Ure Primrose, presiding. This scheme was initiated in the year 1897, when it was proposed to rebuild the front block of the present structure as a memorial of Queen Victoria's Jubilee Reign. For this purpose £86,500 had been obtained, but as the Lord Provost pointed out, it was now felt that reconstruction of the whole building was advisable. What was required for this purpose was an additional £200,000, of which £78,000 had already been contributed by a few citizens, including three subscriptions of £10,000 each. On the motion of Lord Overtoun a committee was appointed to receive contributions to the supplementary fund.

Glasgow Samaritan Hospital Bazaar.

At a meeting of the executive committee of the Samaritan Hospital bazaar held on Jan. 28th, at which the Lord Provost presided, a financial statement was submitted showing that the total receipts of the bazaar amounted to £25,588 and that the expenditure had been £1962, leaving a balance of £23,626 On the motion of the Lord Provost it was agreed in the first place that £20,000 of the free proceeds of the bazaar should be set aside for the purpose of constituting a special endowment fund for the hospital, the annual income accruing from which shall be applied in aid of its maintenance in all time coming. For this purpose the following trustees were appointed—namely, the Lord Provost of Glasgow, the Sheriff of Lanarkshire, the president of the hospital, the chairman of the directors of the hospital, Mr. A. Cameron Corbett, M.P., Mr. John M. MacLeod, C.A., Lady Blythswood, and Lady Ure Primrose, any three of the said trustees being a quorum. It was further agreed that the balance of the free proceeds of the bazaar should be paid over to the directors of the hospital in aid of the building fund in connexion with the new wing about to be erected.

Small-pox in Glasgow.

The total number of patients in Belvidere Fever Hospital on Jan. 29th suffering from small-pox was 241.

Feb. 2nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Central Midwives Board and Irish Midwifery Training.

A REPLY has been sent to the Master of the Rotunda Hospital, Dublin, and to Professor J. W. Byers of Belfast in [illegible] regulations disqualify women trained in the Irish schools of midwifery. The reply of the Central Midwives Board incloses a resolution which was passed by the Board on Jan. 28th to the effect that—

> They regret that the suggested alternatives were not brought to their notice before the rules were sent to the Privy Council, as having been now approved by that body it is impossible for the Board to alter them.

Typhus Fever in Ireland: the Death of Mr. W. J. Coneys.

It was once thought that typhus fever was stamped out in Ireland but such is far from the truth. That disease, which is much the most dangerous and fatal of fevers in this country, prevails in its epidemic form almost every year along the west coast. At such times it is virulent and contagious. It may be remembered that when last it appeared at Clifden four trained nurses were sent from the Mater Misericordiæ Hospital, Dublin. Of these two contracted the disease; they were both very gravely ill and one died. The death of Mr. W. Smyth of Burton Port will be recalled on account of his heroic efforts to bring home and to save his typhus fever patients in the outlying islands in his district in Donegal, which in fact appealed most strongly to the medical profession and to the public. He has been succeeded by a practitioner from Manchester who now cheerfully risks his life out there. Another melancholy death from typhus fever took place recently along the same coast but lower down, in the person of a medical practitioner who contracted the disease in the performance of his duty as dispensary officer for the Roundstone district. Dr. R. J. Kinkead of Galway saw him in consultation with Mr. P. C. Gorham of Clifden and two nurses were summoned by telegraph from Dublin. Nothing availed and Mr. Coneys, who was well known and popular in county Galway, died on Jan. 19th, aged 35 years. His untimely death has caused much grief among the poor people for whom he worked and for whom, indeed, he ultimately sacrificed his life. The following motion was unanimously passed by the Clifden board of guardians:—

> That owing to the sad and lamented death of Dr. Coneys of Roundstone No. 1 Dispensary District who, in discharge of duty, sacrificed his life on behalf of the people who are suffering from a fever epidemic in that district, it is resolved that the business of the board stand adjourned in respect to the memory of this brave man, and we beg to tender our respectful sympathy to his friends and relatives in their sad bereavement.

Clonskeagh Small-pox Hospital.

In the Court of Appeal on Feb. 1st judgment was given in the suit brought by the Attorney-General who sought an injunction to restrain the Rathmines and Pembroke joint hospital board from erecting an isolation hospital for the treatment of small-pox and other infectious diseases on the grounds of Vergemont contiguous to the village of Clonskeagh. The appeal was brought from a judgment of the Vice-Chancellor in which he granted an injunction but only as regards the reception and treatment of small-pox cases. The issue was really a purely medical one for it depended on whether the aerial convection of small pox was proved or was not. The conflicting evidence brought before the Vice Chancellor—and already reported in THE LANCET—from physicians and public health officers was reviewed by Lord Justice Fitzgibbon who stated in his judgment dismissing the action that "he confidently hoped that experience might justify him in declining to accept the theory of aerial convection as against fact so sanctioning an alarm based only upon theory, as the result had justified the decision of Mr. Justice Romer who declined to grant an injunction in a somewhat similar case in Ossett, Yorkshire." Lord Justice Walker and Lord Justice Holmes concurred.

The Provostship of Trinity College, Dublin.

It is said now that the most likely appointment for this most honourable position is Mr. Justice Madden. He is the present Vice-Chancellor and is more ambitious of academic than legal preferment. If, however, a complete outsider is selected rumour points to Professor Butcher, son of the late Bishop of Meath, who is a great personal friend and old Cambridge associate of the present Prime Minister.

Health of Belfast.

The health of Belfast, as disclosed by a discussion in the city corporation on Feb. 1st, is far from satisfactory. 14 cases of small-pox between Dec. 20th, 1903, and Jan. 23rd, 1904, have been notified and since the commencement of this epidemic 35 cases were treated in hospital. Of these 16 have been discharged, 18 remained in hospital, and one (a girl, five years of age, who, owing to bad health, had never been vaccinated) died. There were numerous deaths (59) from whooping-cough 86 cases of scarlet fever, 58 of erysipelas, 27 of typhoid fever, 23 of simple continued fever (whatever disease this may be), 17 of diphtheria, six of puerperal fever, and two of croup were notified. The death-rate was 25·3 from all causes. There is a widespread epidemic of measles and whooping-cough at present in Belfast. It is proposed that the medical officers of health should give certificates in these cases, which it would be necessary to produce before the children were readmitted to the public schools, and to adopt a system of voluntary notification of such complaints as are not legally notifiable.

Attention was rightly drawn to the fact that the public analyst found that the quality of milk supplied to the city of Belfast was deteriorating, due largely to the neglect and apathy, it was said, of the magistrates in not assisting in such cases. The point was of great importance when taken with the fact that one-fourth of the whole mortality last month in Belfast was of infants under one year and almost one half of the deaths were of children under five years. To these children the value of pure milk is of paramount importance. The Dairymen's Association is to have a consultation with the public health committee in reference to the matter. Very strong expressions of opinion were made in reference to allowing the plans of any houses, or rearrangement of houses, to pass which have not provision for back passages.

Mater Infirmorum Hospital, Belfast.

At the annual meeting of the maintenance committee held on Feb. 1st a concert was given to the weekly collectors and workers for this deserving institution. Financially the yield from contributions from business firms was £300. Two wards have been opened for sick children and accident cases from the northern part of the city were conveyed in large numbers daily to the hospital. It is hoped that both workers and employers will contribute to the funds of the hospital.

Queen's College, Belfast.

Mr. Frederick Purser, Fellow of Trinity College, Dublin, has presented a sum of £2000 to the equipment fund of Queen's College, Belfast, to found a studentship in mathematics, in memory of his distinguished brother who was so long on the teaching staff of Queen's College, Belfast, the late Professor John Purser, D.Sc.

Forster Green Hospital for Consumption, Belfast.

At the annual meeting of the friends of this hospital, held on Jan. 28th, it was reported that during the past year there had been 186 intern and 655 extern patients. Necessity of beginning treatment early if satisfactory results are to be looked for was pointed out as well as the proper use of the word "infection" when used in connexion with consumption. Owing to insufficient support more patients were not treated and for the same reason the post of resident physician remains unfilled. Dr. R. M. Beatty has been appointed pathologist. Financially there was a deficit of £235 16*s*. 1*d*. at the close of 1903.

(FROM OUR OWN CORRESPONDENT.)

Medical Men and the Workmen's Compensation Acts.

I HAVE on many previous occasions written about the difficulties which are always arising in France for the medical profession in the working of the Compensation Acts. I have also mentioned the hard-fought battles which take place between the medical defence societies on the one hand to prevent their members being unfairly exploited and the insurance companies on the other which are naturally desirous of profiting by loopholes in the law so as to fulfil their engagements as cheaply as possible and they are backed up in this by the Government which is anxious to curry favour with the working classes by the application of this very contentious law. As is usually the case in all State philanthropic innovations it is the medical men who really pay. The medical defence societies have shown a certain skill in drawing over to their side firstly the working classes, who have the nominal right under the law of choosing their own medical man to attend them in the case of an accident, and secondly the poorer classes, who find themselves at a disadvantage by seeing themselves excluded from the hospitals so as to leave room for injured workmen, and it is certainly an abuse of charity to consider these latter as needy patients for all their expenses are guaranteed by the rich insurance companies Midway between the two camps come the medical officers of the insurance societies whose duties are to report upon an accident and to decide when the injured man is fit to return to work. These medical officers, who are always young and who are only too pleased when confronted with the difficulties of commencing practice to be able to obtain a fixed salary, naturally work in the interests of the insurance societies which are opposed to those of the working man and of his medical attendant. Professor Brouardel has made the grave mistake of intervening on behalf of the companies' medical officers on the hypothesis that in the poor quarters of Paris a fraudulent arrangement might be come to between an injured workman and a needy practitioner to prolong unduly the duration of the former's illness at the expense of the insurance society. This risk, if indeed it exists, is very hypothetical for the insurance companies' medical officer always has the right to inspect the injured man and if he disagrees with the opinion of the patient's medical man as to the duration of the illness he can have the matter decided by the evidence of an official expert (*par un expert assermenté*). The chief question now, however, is the injury caused to hospital physicians and surgeons who have to treat at the expense of the Assistance Publique and without any pecuniary benefit to themselves injured workmen who, had they been treated at home, would have had the fees for treatment paid by the insurance companies. M. Bousquet of Clermont-Ferrand and M. Reynes of Marseilles sent in some interesting reports on the matter to the annual Congress of French Surgery. M. Lande, the Mayor of Bordeaux, who is both a medical man and a member of the Superior Council of the Assistance Publique, has managed to get the administration of the Bordeaux hospitals to agree to pay fees to the hospital medical officers when these latter treat patients whose expenses would be reimbursed to the administration by the insurance companies. Meantime the Society of Paris Hospital Surgeons has not been idle and a committee composed of M. Perier and M. Sebileau has drafted the following resolutions :—

1. That the administration of the Assistance Publique estimate the price charged for hospital accommodation or treatment as an out-patient in the case of injured workmen who cannot be considered as indigent patients.

2. That as regards patients of the above-mentioned class, in addition to the daily charges for food, lodging, drugs, and dressings there shall be added a sum for medical and surgical attendance, such fees to be fixed after the tariff in present use, and that this shall hold good for both in- and out-patients.

3. That the amount of these medical and surgical fees be collected by the Assistance Publique and paid by them into a fund attached to each several hospital, the moneys so paid in to be allocated by the surgeons of the said hospital and divided among charitable institutions or other works of benevolence (in accordance with a schedule drawn up by the committee).

4. That there shall be no special wards for accidents coming under the Compensation Acts, for such a special department would be of necessity prejudicial to the interests of the injured, of the insurance companies, and of the medical men.

The Differences in the N Rays derived from Nervous or Muscular Tissues.

At the meeting of the Academy of Sciences held on Jan. 4th M. Charpentier read a communication which tended to show that physiological radiations are for the most part n rays but that apparently they also contain other radiations. Radiations, for instance, sent out by nervous tissue are partly stopped by aluminium. The radiations which do pass through aluminium will traverse a sheet of that metal even when fairly thick and they are n rays properly so called. On the other hand the sheaf of radiations sent out by the heart, the diaphragm, and other muscles is not affected by aluminium. Another point which distinguishes nervous from muscular radiations is that, as M. Charpentier has previously shown, the former are increased by slight compression whereas the latter are scarcely at all increased by the same means. Finally, the radiations from nerve tissues when compared with those from other tissues affect much more strongly the screen of phosphorescent sulphide when it is heated to a temperature of from 40° to 45° C. It is therefore reasonable to conclude that nervous radiations differ from Blondlot's rays.

Picture Post-cards and the Hospitals.

The administration of the Assistance Publique has just had an idea which will serve to turn to the profit of the sick one of the amusements of modern society. Ten photographs of wards and other interesting places in every hospital have been taken and printed on post-cards. These ten cards are sold by the porters of the several hospitals for 60 centimes the lot and they cannot be bought in the ordinary shops. The profits from this little commercial venture will go to make a sum for each hospital which will be considered as a Samaritan fund for those patients who leave the hospital well in body but friendless and in need.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Abscess of the Lungs.

Professor Hermann Schlesinger recently read a paper on Abscess of the Lungs before the Wiener Medicinisches Doctorencollegium. He said that during the last ten years some progress had been made in the knowledge of the clinical symptoms and the therapeutics of this disease. The non tuberculous forms were caused by pneumonia, the entrance of foreign bodies, traumatism, embolism, perforation of neighbouring ulcers, and bronchiectasis. Among the symptoms which were of diagnostic value might be mentioned the physical signs of cavity and the presence of very abundant, sometimes very offensively smelling, expectoration containing in some rapidly developing cases elastic connective tissue and fragments of lung substance. If there was a spot on the thorax which was at one time tympanitic and at another time dull on percussion, and if the change of sound coincided with the coughing up of large amounts of sputum, this change and the presence of râles would be of diagnostic value in cases of pyrexia combined with ill-smelling sputum. The occurrence of circumscribed dulness amidst the air-containing tissue, a shadow or extremely bright spot shown by means of the Roentgen rays, and portions of lung substance in the sputum were important diagnostic indications. Amphoric breathing was not characteristic for a large cavity. The diagnosis might also be made in cases without pulmonary cavities by observing the increasing circumscribed dulness, the purulent sputum, and the increasing leucocytosis. Up to now the symptom of slowly increasing dulness had not been regarded as significant, but it was of value in the rare cases without expectoration in which no breathing was heard over the area of dulness and this area of dulness was surrounded by normally resonant lung. Pulmonary abscess might be either solitary or multiple; it was mostly in cases of influenza that multiple abscesses occurred. In 80 per cent. of the cases of pulmonary suppuration pleural adhesions were present and might be diagnosed by the imperfect respiratory movement of the lower border of the lung, by the decreased mobility of the individual parts of the thorax, by the condition of *rétrécissement thoracique*, by the drawing in of the skin between the ribs during inspiration, and by the appearances shown with the Roentgen rays. Professor Schlesinger has found inflammatory œdema of the skin (a symptom not long recognised) over the affected part of the lung. Operative treatment was indicated when pulmonary abscess had been diagnosed and its position located, because there was the danger of rapid extension of the process, but operation might be postponed for three or five weeks if the abscess was not putrid. If enlargement of the abscess or perforation into the pleural cavity occurred immediate operation was necessary. It has been found that 80 per cent. of pulmonary abscesses which had been operated on recovered but in cases of gangrene only 60 per cent. of those which were operated on proved successful. After operations for bronchiectasis the results were so unsatisfactory that Professor Schlesinger did not recommend surgical interference in these cases.

Treatment of Sarcoma with the Roentgen Rays.

Dr. Kienböck has had under his care a case of sarcoma of the nose which after the failure of surgical treatment was exposed once a week for three months to the Roentgen rays. The pain disappeared after a short time and the tumour diminished in size. The cause of this improvement was endarteritis obliterans and necrobiosis. Dr. Grossmann has described a case of sarcoma of the nose which was greatly benefited by exposure to the Roentgen rays. Dr. Holzknecht has suggested in reference to cases of sarcoma of the ovary improved by Roentgen rays that there are apparently some kinds of sarcoma extremely sensible to the Roentgen rays and that deep-seated sarcoma not directly exposed to the rays may disappear by absorption through the influence of the small amount of rays passing through thick layers of tissue.

Treatment of Carcinoma of the Œsophagus by means of Radium Rays.

Dr. A. Exner has treated six cases of carcinoma of the œsophagus in the following manner. He fixed an indiarubber capsule containing 60 milligrammes of radium bromide on the general condition improved, because the difficulty of swallowing disappeared. The improvement was caused by breaking down of the carcinomatous tissue, but the treatment was not free from danger because perforation of the œsophagus might occur.

Death of Professor Seegen.

Professor Josef Seegen, celebrated for his researches in connexion with diabetes, has just died at the age of 82 years. A new treatise by him on the Formation of Sugar appeared only a few days before his death.

Feb 1st

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Large Deficit in Hospital Funds.

THE annual statement of the financial affairs of the hospitals of New York makes a very unfavourable showing as to their pecuniary support. For example, the deficit of Roosevelt Hospital was $6000; of St. Luke's, $27,000; of the he Women's, $10,000; of the red and Crippled, $55,675; of of the Lying-in, $88,477; and) hospitals report a deficiency 40 hospitals in the greater city scarcely three or four end the year without a deficit in their funds. From comments on this condition of our great metropolitan hospitals, of which the city may well be proud, we learn that an examination of the methods by which these deficits are met shows that it is mostly done by employing for current expenses legacies and other funds which should be invested for the purpose of making additions to the revenue-yielding capital. If this is the policy pursued these institutions must sooner or later come to bankruptcy. The initial point of departure from a wise policy in the establishment and management of these hospitals is in the construction of the buildings. On purely architectural ornamentation millions of dollars have been expended that might have been saved for endowment or management. There are instances of the expenditure of several millions of dollars of endowment funds on buildings and when the hospitals were opened for the reception of patients there was not a dollar left in the treasury to meet the demands of the management The only suggestion yet made as to the best method of meeting these annual deficiencies of the hospitals is to raise an endowment fund of $10 000,000. No effort has yet been made to accomplish this object and it is doubtful if it can be consummated.

The Public Sale of Depressant Drugs.

The increase of deaths from heart failure has raised the question as to the effects upon the public health of the sale of such remedies as headache powders. In this city in the year 1900 there were registered 4069 deaths from heart disease in a population of nearly 3 500,000; in 1901 the number of such deaths increased to 4626; and in 1902 these deaths reached a total of 5461. The subject came under the notice of the health authorities and early last year an inspection of articles sold as headache powders was undertaken. The result of an analysis of 373 samples of phenacetine showed that only 58 were pure phenacetine, 315 were adulterated with cheaper drugs chiefly acetanilid, 267 specimens contained more acetanilid than phenacetine, and 32 samples were pure acetanilid. The health commissioner published the results of this inspection and announced his determination to expose and to prosecute all druggists found guilty of committing this misdemeanour in the future. It is an important fact that for the year following this threatened prosecution the death-rate from heart failure fell from 1·34 to 1·28 per 1000.

The Results of Treatment of Congenital Dislocations of the Hip.

A report of the orthopædic staff of the Children's Hospital, Boston, throws some new light on the value of Dr. Lorenz's method of treatment of this deformity. The report covers a period of 20 years and 138 cases. In the period previous to 1896 all the 26 cases were failures; in 1896–1902 out of 54 cases treated 12 were successful and only 13 were failures. The year 1902 included those cases treated by Dr. Lorenz and cases treated 11 were successful, four were failures, four ed improvement, and in three the results were unknown. results of treatment in the year 1903 show a remarkable provement, for of 33 cases treated 24 were successful, x failed, and in three the results were unknown. Of the six cases treated by the Lorenz method five were successful and the sixth, being a child nine years old, failed, as was expected. One case treated by incision failed. Much of the success is attributed to the use of a machine invented in Boston, for of the 24 successful cases 18 were manipulated by its aid. In all of the cases treated there was no disaster or fatality.

Tenement House Reform in New York.

The Tenement House Commission has now been in operation for one year and the results of its work surpass public expectation. A summary of its operations shows the need and value of its services in the interests of the poor of the city. Tenement conditions were in many instances found so bad as to be indescribable. Such are vile privies and privy sinks; foul cellars full of rubbish, garbage, and decomposing fæcal matter; dilapidated and dangerous stairs; plumbing pipes emitting sewer gases; living rooms so dark that one could not see the people in them; and pigs, goats, horses, and other animals kept in cellars. The work of the department is thus summarised: 40,000 buildings were inspected, over 80,000 persons were provided with comfortable homes in good sanitary condition, prostitution has been practically abolished in the tenement houses, 337,246 inspections were made, 55,055 violations were filed, 21,584 repairs were made to plumbing, 13,617 water-closets were cleaned, 10 060 unsafe wooden floors were removed from iron fire-escapes and new iron floors were substituted, and 1701 fire-escapes were erected on buildings that were without this protection. The results of this work are clearly reflected in the reduced death rate which in 1902 was 18 7 per 1000 as compared with 20·0 in 1901, and in the first eight months of 1903 it was reduced to 18 per 1000.

The Extermination of the Mosquito.

The war against the mosquito is about to take on national dimensions. The Board of Trade of New York has determined to call a convention for the purpose of concerting measures for a combined onslaught on the mosquito. The promoters of the meeting have requested all departments of health, boards of trade, village and town improvement associations, and medical, entomological, engineering, and agricultural societies to send representatives It is intended to perfect a national organisation for mutual aid in suppressing the mosquito plague. The body so formed will publish and circulate widely a full report of the papers and discussions as a means of arousing and maintaining interest in this subject. In the same connexion may be mentioned the action of the First International Sanitary Convention held in Washington which advised that the different Governments should study in their respective territories the geographical distribution of the mosquito of the genus stegomyia. In compliance with the request the Surgeon-General of the United States Bureau of Public Health has issued orders to the officers of that bureau to collect specimens of all the mosquitoes of the country and to forward them to the entomologist of the United States Agricultural Department, Dr. O. L. Howard, who is engaged in the preparation of a report upon the mosquitoes of North and Central America and the West Indies.

Organised Defence in Suits for Malpractice.

The New York State Medical Association has among its provisions one that enables a member who has been prosecuted for malpractice to appeal to the association to defend him in the trial. The practical result of this engagement of the association in the defence is to bring the profession of the entire State to his support and to relieve him of all responsibility and personal annoyance. The costs of the trial have been reduced to a minimum, as the association has its own attorney who aids the counsel of the physician, or he may assume the duties entirely of the defence. During the two years of the operation of this provision many suits have been defended and every one successfully. When the proposition was first made to make it an obligation of the association to assume the defence of members prosecuted for malpractice the scheme was regarded as not only impracticable but likely to induce patients to prosecute and thus to increase rather than to mitigate the evil. The effect has been found to be the opposite; prosecutions are diminishing and apparently because it is becoming known that the physician prosecuted does not stand alone but, on the contrary, has the actual support and protection of a powerful organisation which represents the profession of the State.

The New Naval Medical School.

The Surgeon-General of the United States navy speaks in the warmest terms of the Naval Medical College at Washington in his annual report to the Congress It was organised under department orders of May 27th, 1902, and closed its first session on April 27th, 1903, by the graduation of its first class of 12 members. The course of instruction is designed to instruct and to train newly appointed medical officers in professional branches peculiar to naval requirements and in the methods of naval work as applied to their profession and in general. The need of a preliminary course of instruction for the novitiate of the medical corps before taking up active duty was fully demonstrated in the class work, and already in the few months since graduation during which the members of the class have been actively employed the value of this school training has been practically demonstrated.

Jan. 20th.

Obituary.

WILLIAM DONALD, M.D. ABERD.

MUCH and sincere regret is felt in Banff and neighbourhood at the death of Dr. William Donald which occurred in Aberdeen on Jan. 18th. For about a year he had been suffering from a very painful internal malady and about two months ago it was found necessary to have him removed to Aberdeen for the purpose of undergoing a surgical operation. This was successfully performed and for a time gave the patient relief, but after this he took a turn for the worse and rapidly lost strength.

Dr. Donald was the eldest son of William Donald, M D, Bogside of Eden, King Edward, Aberdeenshire, and graduated at the University of Aberdeen as M B. and C.M. in 1873. He passed the next few years in Banff where he was resident surgeon in Chalmers' Hospital. From Banff he went to Colombo, Ceylon, where he was district medical officer for several years and married Miss Deane, only daughter of the late Captain H. Deane, Banff. Returning from Ceylon about 26 years ago Dr. Donald settled in Banff and in time made for himself a large practice throughout an extensive district. He held many local appointments, among others those of visiting surgeon to the Chalmers' Hospital, Banff, certifying surgeon under the Factory Act, and lieutenant-surgeon of the Macduff Artillery. He was a justice of the peace of the county and was for many years an elder in the parish church. In public affairs Dr. Donald took a very keen interest and for a term of years was a member of the School Board. He was 51 years of age at the time of his death and is survived by a widow and grown-up family for whom much sympathy is expressed.

Medical News.

UNIVERSITY OF OXFORD.—The following dates are fixed for degree days: Hilary term, Thursday, March 17th; Easter term, Thursday, April 28th, and Thursday, May 19th; and Trinity term, Thursday, June 16th, Thursday, June 23rd, and Saturday, July 9th. The following degrees have been conferred:—

B.M., B.Ch.—Dec. 10th, 1903: Henry Wynyard Kaye, Magdalen. Jan. 21st: Douglas Reginald Pike, Jesus; Frederick Pitcairn Nunneley, Brasenose; Frederick Lucien Golla, Magdalen; Conrad Meredyth Hinds Howell, Trinity; Paul Norman Blake Odgers, Lincoln; and Alexander George Gibson, Christ Church.

The examination for the Radcliffe travelling fellowship will commence on Tuesday, March 1st. The names of intending candidates must be sent in to the "Radcliffe Examiners," University Museum, Oxford, on or before Tuesday, Feb. 9th.

UNIVERSITY OF CAMBRIDGE.—His Majesty the King has graciously announced his intention of visiting the University on March 1st for the opening of the new Medical

School, Botanical Laboratory, Sedgwick Memorial Museum, and Law School.—At the congregation on Jan. 28th the following medical and surgical degrees were conferred :—

Doctor of Medicine.—J. R. Garrood, St. John's; and E. M. Light, Clare.
Master of Surgery.—J. K. Murphy, Gonville and Caius.
Bachelor of Medicine and Bachelor of Surgery.—R. E. V. Foster, King's; and W. Hill, Emmanuel.
Bachelor of Surgery.—C. F. Hardie, Queen's; H. R. Fisher, Emmanuel; and B. J. Steward, Downing.

Dr. H. K. Anderson has been appointed university lecturer in physiology in the room of Dr. J. N. Langley, resigned, on appointment to the professorial chair.—The report of the special board for medicine, proposing the establishment of a special examination and a university diploma in tropical medicine and hygiene, was on Jan. 28th adopted by the Senate.

CONJOINT EXAMINATIONS IN IRELAND BY THE ROYAL COLLEGE OF PHYSICIANS AND ROYAL COLLEGE OF SURGEONS.—The following candidates have passed the examinations indicated :—

Second Professional Examination.—(a) *First trial*: F. F. Gilligan [illegible] Wallace.
Third Professional Examination.—(a) *All subjects*: M. Campbell, C. L. Browne, George Thomason, and C. H. Twells. (b) *Completing*: A. C. Adams, M. Antony, F. L. Bradish, W. C. Carson, E. Duffy, J. C. Heelan, Miss Lardner, James Roberts, P. P. Ryan, R. H. Smythe, and W. Tobin.
Fi[illegible] *All subjects*: C. L. Browne. (b) *Completing*: R. G. Allen, [illegible] Kelly, Thomas Kelly, John [illegible] W. W. Stuart, and Miss A. Taylor.

SHELL-FISH.—A conference of oyster merchants and others interested in the shell fish industry will be held at the Great Eastern Hotel, Liverpool-street, London, to-day (Friday, Feb. 5th), at 11 A.M. Mr. D. J. Morgan, M.P., will preside and the business will be to consider the recent report of the Royal Commission on Sewage Disposal bearing upon the protection of shell-fish layings.

LONDON HOSPITAL MEDICAL CLUB.—A meeting of the executive of the above club was held on Jan. 26th to formulate the rules and regulations to be submitted for acceptance by the members for the formation of a benevolent scheme in connexion with the club. Several subscriptions have already been promised and it is believed that the movement will not only prove successful but that it will be the pioneer of similar plans being carried out in connexion with the various medical schools throughout the entire country. The London Hospital Medical Club has now been in existence for over a century. It is not proposed to alienate any of the present funds of the club and all subscriptions are to be carried to capital account, the interest of which alone is to be applied to benevolent purposes.

LECTURES ON MEDICAL JURISPRUDENCE.—The third of the interesting series of lectures under the auspices of the Council of Legal Education was delivered on Jan. 28th at the Old Hall, Lincoln's Inn, by Dr. F. J. Waldo, coroner of the City of London, the subject being Death in its Medico legal Relations. This was a matter of considerable importance to the legal profession. The possibility of live burial was dismissed shortly by the lecturer with the statement that from a scientific point of view it might be said that no recorded case bore the scrutiny of exhaustive logical inquiry. It was often of considerable importance both in civil and in criminal cases to determine the exact moment of death. At the same time speculations of this kind were often of theoretical rather than of practical value. Of the signs of death no one could be taken as absolutely conclusive of the precise moment at which somatic or general cessation of life had taken place. Putrefaction, again, although a certain sign of death, could not be regarded as a precise index of the time that had been taken up in the process. Thus it would be impossible to say in many instances whether a given body had been that of a person dead one or six months. Fallacies on this point were numerous. For instance, putrefaction might be considerably delayed in the case of persons who had been confirmed alcoholics or who had been poisoned with antimony, or whose bodies had been immersed in water. The lecturer concluded by various practical recommendations as to desirable reform in the present system of death certification. One of the chief points was the registration of all still-born children by a duly qualified medical practitioner; otherwise the body of such an infant should be buried only upon the order of a coroner. Other important suggestions were made as to the causes of death that should be investigated by the coroner. The lecture, which proved both practical and interesting, dealt with the subject rather more from the point of the well-informed medical jurist than from that of the legal.

DONATIONS AND BEQUESTS.—Under the will of [illegible] *to the Ulverston* [illegible] to Bolingbroke [illegible] resented £350 to the committee of the Tiverton Infirmary, Devon, for the purpose of providing a laundry for the institution.

NEWPORT MEDICAL SOCIETY.—A meeting of this society was held in the Newport and County Hospital on Jan 27th. There was an exhibition of clinical cases and specimens. Major H. B. Mathias, R.A.M.C., read notes on a case of Splenic Anæmia in which trypanosomes were found in a smear preparation taken from the spleen after death. Mr. W. Sheen read a paper on Radium and its Possible Therapeutic Uses. The exhibits and papers were discussed by the members present.

INSTITUTE OF CHEMISTRY OF GREAT BRITAIN AND IRELAND.—In the Intermediate Examination held on Jan. 5th–8th 15 candidates presented themselves and 11 passed. In the Final (A.I.C.) Examination in Branch A, Mineral Chemistry, six candidates presented themselves and four passed. In Branch D, Organic Chemistry, 11 candidates presented themselves and six passed. In Branch E (the Analysis of Food and Drugs, including an examination in Therapeutics, Pharmacology, and Microscopy) four candidates were examined and three passed. Of three candidates examined for the Fellowship (F.I.C.) two were successful. The examiners in general chemistry were Mr. W. W. Fisher, M.A., F.I.C., and Professor W. Palmer Wynne, D.Sc., F.R.S., F.I.C.; and the examiner in therapeutics, pharmacology, and microscopy was Dr. Arthur P. Luff, B.Sc.

PRESENTATIONS TO A MEDICAL OFFICER OF HEALTH.—On Jan. 28th Mr. John Robertson, M.D., B.Sc. Edin., until recently medical officer of health of the city of Sheffield and now holding a similar appointment in Birmingham, was entertained at dinner by members of the medical profession and by his late colleagues on the staff of University College, Sheffield. Mr. R. J. Pye Smith, in presenting him with a silver James I. tea tray on behalf of the council and staff of University College, spoke in enthusiastic terms of Dr. Robertson's services to that institution as professor of public health and lecturer on bacteriology during the past six years. Dr. Robertson was also the recipient of a silver rose-bowl which was presented on behalf of the medical profession of Sheffield in recognition of his valuable services to the city as medical officer of health by Councillor Dr. E. Hargreaves.

BALNEOLOGICAL CONGRESS AT AACHEN (AIX-LA-CHAPELLE).—The twenty-fifth Balneological Congress will be held at Aachen from March 3rd to 7th, under the presidency of Herr Liebreich of Berlin. A number of interesting addresses will be delivered. The physicians and civic authorities of the town have taken the liveliest interest in the preparations for the Congress and are prepared to extend a hearty welcome to their medical guests. The opening reception will be held at the Kurhaus at 8 P.M. on Thursday, March 3rd. The Congress will open at 10 on the following morning with speeches from Herr von Hartmann, "Regierungs Präsident"; Herr Veltmann, "Oberbürgermeister"; Dr. Breuler, rector of the "Hochschule"; Dr. Beissel, "Sanitätsrath"; and others. During the Congress papers will be read by Herr Polis of Aachen o[illegible] the Rhine Provinces; by Herr [illegible] Rheumatism in the Joints; by [illegible] the Climatic Treatment of Heart Complaints; by Herr Kugler of Marienbad on Balneo physics and Climatic Health Resorts, and many others. Several receptions will be arranged and on the last evening there will be a special performance of Haydn's *Creation* in the large concert room of the Kurhaus. Further particulars will be supplied by Herr Sanitätsrath Dr. Beissel, 18, Kleinkolnstrasse, Aachen.

Parliamentary Intelligence.

Opening of the Session.

The session of Parliament was opened on Tuesday, Feb. 2nd, by His Majesty the King, who was accompanied by Queen Alexandra. The opening ceremony took place in the House of Lords in presence of a large gathering of peers and members of the House of Commons and other privileged persons. In the speech delivered by His Majesty legislation was promised with reference to the immigration of criminal and destitute aliens into the United Kingdom, the issue of liquor licences in England, the housing of the working classes in Ireland, the law of public health, the hours of employment in shops, and a number of other subjects The opening proceedings lacked the presence of the Prime Minister who was suffering from an attack of influenza.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Atkins, S. E., L.R.C S.I., L.S.A., has been appointed Certifying Surgeon under the Factory Act for the Hatherleigh District of the county of Devon.

Beresford, R. de la Poer, M.D. Glasg., has been appointed Medical Examiner of Recruits for the Montgomery Imperial Yeomanry at Oswestry.

Corner, Edred M., M.B., B.S. Cantab., F.R.C.S. Eng , has been appointed Assistant Surgeon to St. Thomas's Hospital.

Fry, W. W. B., M.B., C.M. Edin , has been appointed Medical Examiner of Recruits for the Montgomery Imperial Yeomanry at Builth Wells.

Humphreys, C. E., M.R.C.S., L.S.A., has been appointed Medical Examiner of Recruits for the Montgomery Imperial Yeomanry at Llanfair.

Jones, F. F., M.R.C.S , L S.A., D.P.H., has been appointed Medical Examiner of Recruits for the Montgomery Imperial Yeomanry at Llanfyllin.

Kenwood, H. R., M.B., C M. Edin., D.P.H., has been appointed Professor of Hygiene and Public Health at University College, London.

Murray, J., M.B., C.M. Glasg., has been appointed Medical Examiner of Recruits for the Montgomery Imperial Yeomanry at Llandrindod.

Pringle, J., M.D., has been appointed Certifying Surgeon under the Factory Act for the Manchester, S.W., District of the county of Lancaster.

Procter, Thomas, M.R C.S., L.R.C.P. Edin., has been appointed Medical Officer and Public Vaccinator for the Fifth District of the Chipping Sodbury Union.

Richardson, F. L. C., L.R.C.P. & S. Edin., has been appointed Medical Examiner of Recruits for the Montgomery Imperial Yeomanry at Rhayader.

Salter, F. W., L.R.C.P. & S. Edin., has been appointed Medical Examiner of Recruits for the Montgomery Imperial Yeomanry at New Mills.

Scott, Sydney, B.S. Lond., F.R C.S. Eng., has been appointed Honorary Surgeon to the Westminster General Dispensary, London, W.

Smith, William Robert, M.D., B.S. Lond., F.R.C S. Eng., has been appointed Assistant Surgeon to the Hospital for Women, Nottingham.

Wilson, F., has been appointed Medical Examiner of Recruits for the Montgomery Imperial Yeomanry at Newtown.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Ancoats Hospital, Manchester.—Resident House Physician. Salary £80 per annum, with board, residence, &c.

Birkenhead Union Infirmary, Workhouse, and Sanatorium.—Resident Assistant Medical Officer. Salary £120 per annum, with board, washing, and apartments.

Birmingham, Queen's Hospital.—Two House Surgeons, for six and twelve months respectively, and one House Physician, for twelve months. Salaries at rate of £50 per annum, with board, lodging, and washing. Also one Obstetric and Ophthalmic House Surgeon for six months. Salary at rate of £40 per annum, with board, lodging, and washing..

Bristol Royal Infirmary.—Resident Junior House Surgeon and Anæsthetist; also Resident Casualty Officer, both for six months. Salaries at rate of £50 per annum, with board, lodging, and washing.

Camberwell House Asylum.—Second Assistant Medical Officer, unmarried. Salary £150 per annum, with board, residence, and laundry.

Cancer Hospital, Fulham-road, London, S.W.—Surgical Registrar. Honorarium £26 5s. per annum.

Carmarthenshire Infirmary.—Resident Medical Officer, unmarried. Salary £100 per annum, with apartments, board, attendance, &c., for twelve months, one month's notice.

Carmarthen, Joint Counties Asylum.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, with board, apartments, and washing.

Central London Ophthalmic Hospital, Gray's Inn-road, W.C.—Assistant Surgeon.

Charing Cross Hospital.—Medical Officer in charge of the Electrical Department. Also Assistant Physician to Dermatological Department.

Coventry and Warwickshire Hospital.—Assistant House Surgeon Salary £60 per annum, with rooms, board, washing, and attendance.

Dudley, Guest Hospital.—Senior Resident Medical Officer. Salary commencing £100 per annum, increasing to £120, with board, residence, attendance, and washing.

Gloucester, Barnwood House Hospital for Mental Diseases.—Junior Assistant Medical Officer. Salary at rate of £150 a year, rising to £170, with board, &c.

Gloucester General Infirmary and Eye Institution.—Assistant House Surgeoncy for six months. Remuneration at rate of £30 per annum, with board, residence, and washing.

Holloway and North Islington Dispensary, Holloway road, N.—Honorary Medical Officer.

Hospital for Diseases of the Skin, 52, Stamford-street, Blackfriars, S.E.—[illegible]

Hospital [illegible] London, W.—House Physician for six m[illegible]

Kettering and District General Hospital.—Resident Medical Officer, unmarried. Salary £60 per annum, with board, residence, &c.

Liverpool, Royal Southern Hospital.—Junior House Surgeon. Salary 60 guineas per annum.

Macclesfield General Infirmary.—Junior House Surgeon. Salary £70 per annum, with board and residence.

Manchester Hospital for Consumption and Diseases of the Throat and Chest, Hardman-street, Deansgate, Manchester, and Bowdon, Cheshire.—Honorary Assistant Physician.

Metropolitan Hospital, Kingsland-road, N.E.—Assistant Surgeon

Middlesbrough, North Riding Infirmary.—Assistant House Surgeon, unmarried. Salary £75 per annum, with bed, board, and washing.

National Hospital for the Paralysed and Epileptic (Albany Memorial), Queen-square, Bloomsbury.—Junior House Physician Salary £50 a year, with board and residence.

Oxford, Radcliffe Infirmary.—House Physician (salary at rate of £80 per annum), and Junior House Surgeon (salary at rate of £[illegible] per annum), each for six months, and unmarried.

Paddington Green Chil[illegible]n, W. Convalescent Home, "Fair View," S[illegible] to Out patients

Robert Browning Settl[illegible]—Honorary Medical Officer during absence of Medical Superintendent.

Sheffield City Hospital for Infectious Diseases.—Second Assistant Medical Officer. Salary £150 per annum, with board, lodging, and attendance.

Tottenham Hospital.—House Physician for six months. Salary £[illegible] per annum, with board, residence, and laundry.

Wigan, Royal Albert Edward Infirmary and Dispensary.—Junior House Surgeon. Salary £80, with board, apartments, and washing.

Worcester General Infirmary.—House Surgeon. Salary £70 per annum, with board and residence.

The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory Act at Addingham in the county of York, and at Alfreton, in the county of Derby.

Births, Marriages, and Deaths.

BIRTHS.

Brend.—On the 28th Jan., at 43, Campden-hill-court, Kensington, W., the wife of William A. Brend, M B., of a son.

Jackson.—On Jan. 31st, at the Lings, Radcliffe on-Trent, the wife of Arthur M. Jackson, M.D. Oxon., of a son.

Nash.—On Jan. 29th, at Southend-on-Sea, the wife of J. T. C. Nash, M.D., Medical Officer of Health, of a daughter.

MARRIAGE.

Nixon—Stow.—On the 16th Dec., 1903, at the Parish Church, Roodepoort, Edward John Nixon, J.P., District Surgeon, Heidelberg, Transvaal, to Nellie Philipson Stow, R.R.C., daughter of the late George W. Stow, F.R.S.

DEATHS.

Clarke.—On 16th ult., the wife of Fielding Clarke, M.R C S Eng., etc., at Tunbridge Wells, of typhoid.

Miller.—On Jan. 25th, at "Abingdon," Ryde, Isle of Wight, James Miller, L.F.P.S. & L.M. Glasg., L.S.A.L., late of 136, South Lambeth road, S.W., aged 59.

Playfair.—On the 1st inst., at Bournemouth, David Thomson Playfair, M.D., of Bromley, Kent, elder son of the late Rev. David Playfair, of Abercorn, N.B., aged 48.

Raitt.—On the 28th ult., at Prestwich, Manchester, Thomas Raitt, M.D., aged 55.

Withecombe.—On Feb. 1st, at Richmond, Surrey, John Rees Withecombe, M.D., F.R.C.S., Bengal Army (retired), aged 87.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

GUY'S HOSPITAL AND THE SOUTHWARK GUARDIANS OF THE POOR.

An interesting article, portions of which we reprint below, appears in the *Guy's Hospital Gazette* of Jan. 30th. As will be seen it deals with a recent "Hospital Scandal" so called:—

> "I [illegible] m [illegible] recei [illegible] being no bed available for his reception, was sent in a cab to St. George's Workhouse with a recommendation for his admission into that institution. This proper and considerate action on the part of the house surgeon the Southwark guardians chose to regard as a 'scandal,' and proceeded to make an unjust charge against the hospital with such noise and violence as to deceive a large section of the press into accepting the charge as true and publishing it accordingly, with very harmful results to the cause of this great charity.
>
> Now with regard to this particular case, the course followed by the hospital is adequately vindicated by the fact that all its surgical beds were full. The wards at Guy's are not constructed on the principle of concertina, and the strict regulation of the governors against the putting up of extra beds with all the attendant evils of overcrowding is beyond criticism. There is nothing humane or sensible in attempting to cure one evil by the creation of another and a worse. Moreover, it may be remarked that the case in point was one with which the officials of the workhouse, with the assistance of their medical officer, should have been perfectly capable of dealing, and it would appear, when they were put to it, that they did do so. The guardians, however, have stated that the matter is not to be allowed to rest here. Neither, we hope, is it the intention [illegible] it should; and we take this [illegible] upon certain facts which the [illegible] ignore. That body apparently assumes that Guy's hospital exists and is supported for the especial benefit of the borough in which it is situate. In this they are quite mistaken. Whether honest or not the assumption is false. But for the sake of argument assume it to be true and let us see how Guy's fulfils its obligations to Southwark."

The article then goes on to state that the hospital pays some £3000 a year in local rates; that of the 125,000 out-patients yearly attended to by far the larger proportion comes from Bermondsey and Southwark; that there is a regulation requiring the Poor-law guardians to pay 2*s.* per diem for any Poor-law case in the wards and that this regulation has never yet been met by the Southwark authorities; finally, that the contribution of Southwark in 1903 towards the support of Guy's Hospital was £277. The article continues:—

> "But if the guardians are beaten on their own ground, as they unquestionably are, by the force of concrete facts, they are yet more hopelessly astray when the case is judged, as it should be judged, on the principle. May we be excused for reminding the guardians, or informing them if they are unacquainted with it, of the existence, intent, and provisions of the statute under which they hold sway. So long ago as the year 1601 the legislature of this realm adopted the principle that no necessitous person was to suffer want either in hunger or sickness and proceeded to enact a measure, still in force, known as the Act of Elizabeth and constituted an authority charged with the duty of giving effect to the measure. That authority in Southwark is not Guy's Hospital but the guardians of the poor, and the existence of the hospital does not relieve them from their own legal responsibility. If the arrangements at St. George's workhouse are so bad as not to enable the guardians to deal with the sick cases which properly come within their province those arrangements need altering and we make the friendly suggestion that they should establish a reception station at the workhouse where such cases can be retained until it is possible to safely transfer them to the Infirmary at Champion Hill. At any rate, it should be understood that Guy's Hospital will continue to send to the workhouse cases which the hospital cannot accommodate and which need shelter and medical attention, and if the guardians neglect to properly deal with these cases it will rest with the hospital to refer their dereliction of duty to the Local Government Board."

LICENCES FOR THE SALE OF COCAINE IN INDIA.

We have received a copy of a petition which has been addressed by the Ahmedabad Medical Society to the Governor-General of India in connexion with the recent order of the Government requiring medical practitioners to obtain licences for which an annual fee of one rupee is charged for dispensing cocaine to their patients. The petitioners assume that the object of the Government is not so much to find a new source of revenue as to put a stop to the pernicious habit of cocaine-eating, and they accordingly adduce a variety of arguments against the order in question. The society is in complete sympathy with measures directed against the abuse of cocaine by the general public and points out that the object of the order complained of would [illegible] no general medical practi- [illegible] no specialist in diseases of [illegible] e ounce of cocaine for dispensing to patients during the course of one year, except with a special licence.

THE "COLMO" DISINFECTOR.

This is an ingenious and simple little appliance for the automatic supply of a disinfectant fluid to the flush water for the water-closet. It consists of a block encased in tinned iron containing a glass vessel into which crystals of permanganate of potassium are placed. By the alternate rise and fall of the water in the cistern the glass vessel is charged with water which dissolves part of the permanganate of potassium. When the cistern is emptied a solution of permanganate is automatically syphoned out of the glass vessel and a disinfectant flush is discharged into the pan. The method has obvious advantages, the most important being that the water in the trap is kept sweet and clean, while should any gases escape backwards through the trap they come into contact with the disinfectant and are to some extent deodorised. A drawback, however, to the use of permanganate of potassium as a disinfectant in the closet pan is its tendency to deposit a brown stain upon the enamel. The dis- [illegible]

Old Ford, E.

A QUACK'S LECTURE.

The *Accrington Observer* of Jan. 23rd contains an account of a lecture delivered at the Accrington town hall on the subject of "Our Diseases," by "Mr. George Hall of Dr. Hall's Hygiene Co., Manchester." Whatever Mr. Hall's views may be upon the causation and cure of disease, he is apparently not averse from using the title of "doctor" in order to advertise his pretensions to deal with it, although no doubt he considers that the words added veil his offence and do not "*imply that he is a registered person.*" The nature of the nonsense which the local newspaper reproduced in a condensed form may be gathered from the following extracts. Mr. Hall of "Dr. Hall's Hygiene Co." is stated to have "in vigorous style declared his object was to show a better way of curing disease than by drugs and butchering." "Indigestion and constipation were the parent of all their diseases and every tumour, cancer, fever, and disease known were attributable thereto." "Cancer in the breast could be cured in most cases by pure herbs within and without, good food, and honest living." "Any case of appendicitis could be cured in one day with herbs and without any operation." The worst of this kind of thing is that it is not only delivered to an audience of uneducated and unintelligent persons but is believed in at least by some of them and that the law claims no power to save foolish people from their own folly or to protect them from any glib-tongued mountebank who may impose his absurdities upon them.

DEATH CERTIFICATES FOR INSURANCE COMPANIES.

To the Editors of The Lancet.

Sirs,—Many insurances offices require special forms of certificates of deaths of their policy holders. Who ought to pay the fees for these certificates, the office or the executors? What is the usual fee?

I am, Sirs, yours faithfully,
Qui deo.

Feb. 2nd, 1904.

⁂ The general custom is, we believe, for the executors to pay a fee of one guinea It is obviously to the interest of the executors to obtain the sum insured for, in the interest of the legatees, and it is they therefore who should pay the fee.—Ed. L.

FASHION PAPERS AND MEDICAL ADVICE.

We have received a copy of a fashion paper called *Myra's Journa* against which as a fashion paper we have nothing to say. But we cannot think that the editor is wise in accepting advertisements of "Towle's P. & S Pills," which are indubitably used to procure abortion, although we do not presume that in 99 cases out of 100 the desired result would be secured. We commend to the notice of the editor the issues of The Lancet of Dec. 10th, 17th, 24th, and 31st, 1898, and Jan. 21st, Feb. 4th, and especially June 24th, p. 1740, 1899, where he will find an account of Towle's pills. On p. 46 [illegible] which is dated Feb. 1st, [illegible] "con- [illegible] other matters connected with personal appearance. Two correspondents are, however, much troubled about the size of their mammary glands. "Miss Fatima" is too big and "Undine" is too small. To the former the writer of the article recommends "Dr. Horn's Reducing Paste," to be obtained from Dr. Otto E. Horn, Bournemouth. The following somewhat mysterious directions are given for its use. "Warm a little of this in the palm of one hand, then apply it with circular movements of the finger tips of the other, beginning underneath and working upwards until the skin has absorbed all it can." Now we know nothing of Dr. Horn or his paste but we are quite certain that the treatment recommended will not aid "Miss Fatima" in any way. "Undine" is recommended to apply to the Espanola Medicine Company for the Diano treatment. Now The Espanola Medicine Company is run by A. L. Pointing, concerning whom we have had a good deal to say recently, and so has our contemporary, *Truth*. The Diano treatment is nothing more or less than a fraud and for a respectable journal like *Myra's Journal* to admit such advertisements as Towle's or to recommend its clients to go to a man like Pointing is disgraceful.

THE INJURY TO MADRALI.

To the Editors of THE LANCET.

SIRS,—I was present at the contest between Hackenschmidt and Madrali for the "wrestling championship" on Saturday last. I examined Madrali's injured arm on the platform and afterwards in the dressing-room. Madrali was suffering from a severe injury of his right elbow-joint resulting from a fall on his hand accompanied by a twist. As a consequence there was an irregular and partial dislocation of the right elbow with some rupture of ligament, the radius coming forwards and the ulna going backwards. It is impossible to say exactly how long it will be before he recovers, but I should think in six weeks he will be quite well and in two months it would be safe for him to wrestle again.

I am, Sirs, yours faithfully,

Kensington, W., Feb. 2nd, 1904. F. G. LLOYD.

THE LAY PRESS AND MEDICAL TERMINOLOGY.

WE have often had good reason to call attention to the extraordinary errors into which certain of the daily papers fall in their use of medical terms. When describing the nature of the illness of His Majesty the King, for instance, some bewildering errors were made by papers taking a high position in the journalistic world. One first-class paper mistook the liver for the kidney, others thought that suturing drainage tubes was necessary to preserve continuity of gut. We thought that the climax of absurdity had been reached in this way, but an instance of the danger of using technical terms when the user is ignorant of their meaning which now lies before us is in some ways the most ludicrous that we have ever seen. In the issue of the *Express* of Jan. 29th is a paragraph concerning the scarcity of bodies for dissection in Scotland. The writer of the article in question finishes his statement as follows: "They"—i.e., bodies for dissection—"are kept in spirits and anæsthetised. The latter process is now made imperative as in years gone by students have contracted fatal blood poisoning during the process of dissection." To try to anæsthetise a dead body seems a work of supererogation. What does the writer think the word "anæsthetised" means?

THE OXYGEN TREATMENT.

A CORRESPONDENT asks:—"Can anyone favour me with details of the oxygen treatment for chronic ulcers or refer me to literature on the matter?"

◆

Quack.—The "Famous Specific" in question is composed of alum, borax, and sulphate of soda, made up *in a fatty vehicle. If there* were nothing the matter no particular harm would result from using the stuff, although the unnecessary employment of applications to the vagina is always to be deprecated. If any diseased condition existed the application would be perfectly useless.

Indibis.—The "Professor" is an obvious and rampant impostor. If the electric machine, price £8, which cures stammering would really do its work in a month he would be perfectly happy to be paid at the end of the month by a grateful patient. As, however, he knows that the machine, which, by the way, is probably not worth more than 8s., can do no good he is careful to take his money first.

F. J. F.—1. The position of such men would be very precarious. Their action would possibly be construed by the General Medical Council as "covering," and result in their removal from the Register. 2. He was removed for advertisement of a sort which was considered by the General Medical Council to constitute infamous conduct in a professional respect. 3. We do not know.

R. W. G.—The assistant can only be employed in accordance with the regulations of the General Medical Council.

Etc.—We have read the article. There is a considerable amount of rubbish enveloping its modicum of sense.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received: *The Star (Guernsey), Muswell Hill Times, Hertfordshire Mercury, Windsor and Eton Express, Standard, South Wales Daily News, Walsall Advertiser, Surrey Advertiser, Coventry Herald, Birmingham Daily Mail, Reading Mercury, Mining Journal, Local Government Chronicle, Liverpool Courier, Westminster Gazette, Pall Mall Gazette, Daily News, Irish Times, Nottingham Guardian, Aberdeen Free Press (Weekly), Highland News, &c.*

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1903, which was completed with the issue of Dec. 26th, were given in THE LANCET of Jan. 2nd, 1904.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1903 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

A.—Messrs. Arnold and Sons, Lond; Ancoats Hospital, Manchester, Secretary of; A. B. C.

B.—Major G. Bent, R.A.M.C., Warwick; Messrs. Burroughs, Wellcome, and Co., Lond.; T. B. Browne, Ltd., Lond.; Messrs. Baillière, Tindall, and Cox, Lond.; Dr. Butler-Hogan, Lond.; Dr. E. Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

Cheques and Post Office Orders (crossed "*London* and *Westminster* Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31 Rue Bapts, Asnières, Paris.

A Clinical Lecture

ON

A CASE OF ADAMS-STOKES DISEASE

(PERSISTENT SLOW PULSE WITH EPILEPTIFORM FITS).

Delivered at the London Hospital on Oct. 28th, 1903,

By PERCY KIDD, M.A., M.D. Oxon., F.R.C.P. Lond.,

PHYSICIAN AND LECTURER ON MEDICINE TO THE LONDON HOSPITAL.

GENTLEMEN,—The patient, a woman, aged 58 years, has been ill for about four years and complains of symptoms which may be briefly summarised as follows: weakness, fainting fits, vomiting, swelling of the feet and legs, headache, sharp pain round the heart, slight hacking cough, occasional night sweats, swelling of the abdomen at times, and increasing stoutness. She has not had rheumatic fever but she had scarlet fever when a child. Fifteen years ago she had influenza very badly; she has had it four times since but mildly. She had small-pox 30 years ago. The patient is a stout, flabby-looking woman and is very pale. She complains of dyspnœa, especially on exertion, and of fainting fits usually brought on by exertion or excitement The first fit occurred five years ago and since then she has been unable to go out alone in consequence.

The following is a description of the fits. There is no warning; they have always the same character; the duration varies from two or three minutes to half an hour. She has had from five to six fits in a day at times, though they may be absent for weeks. Sometimes on recovering from one fit she immediately has another. She also complains of pain in the region of the heart which is described as sharp but the pain does not radiate. She often has the pain without the fits, though at times the pain comes on as the fit is passing off. The pulse on admission varied from 25 to 28 The tension was moderate and the artery was not thickened. The heart's impulse was not felt. The apex beat was apparently in the nipple line in the fifth space. Cardiac dulness was slightly increased outwards but not in other directions. On auscultation a faint systolic murmur was heard replacing the first sound in all areas; it was loudest at the mid-sternum, about the level of the third rib. The second sound was present in all areas, occasionally reduplicated. Vomiting occurred occasionally, usually after food but often on rising in the morning; it sometimes occurred as the fit was passing off. The vomit was watery, sometimes coloured yellow with bile. The urine was healthy. The menopause occurred nine years ago

The patient's general condition did not vary much at first but a few days after admission a fit occurred and was observed by the clinical clerk, Mr. M. Wyler, whom I have to thank for his careful notes. The patient suddenly cried out, her head was retracted, the pupils were widely dilated, the face was cyanosed, and the pulse was imperceptible for 40 seconds. She was quite unconscious, her whole body being rigid and extended Incontinence of urine occurred and as she gradually recovered retching took place. On recovery the pulse rose to 52. The whole fit lasted for five minutes. In another fit a few days later the pulse ceased for 90 seconds and this fit lasted for three minutes.

At first the patient was treated with strychnine, ether, and ammonia. Later, $\frac{1}{100}$th of a grain of trinitrine was substituted three times a day and occasional inhalations of amyl nitrite. After this $\frac{1}{60}$th of a grain of strychnine was given hypodermically three times a day. Latterly she was given thyroid extract, three grains in the day, which was gradually increased to 15 grains daily. Two ounces of whisky were allowed and the patient was put on light solid diet. She has improved in all respects since her admission There are less dyspnœa and cardiac pain and she has only had one slight attack subsequently to the two previously described. The thyroid extract was given at the suggestion of Dr. O F. F. Grünbaum, our medical registrar who had seen it recommended by a French observer, Dr. Gautier. It is doubtful whether the improvement can be attributed to the use of thyroid extract as nitro-glycerine and strychnine were being administered at the same time. Subsequently the patient was for a time put on thyroid extract and nitro-glycerine separately and continued to improve steadily. She now takes an occasional trinitrine tabloid and has had no epileptiform attack for over two months. At times she experiences a slight pain in the cardiac region.

The foregoing curious group of symptoms was first described by Robert Adams in the Dublin Hospital Reports[1] in 1827. Adams described the following case. A man, aged 68 years, of full habit, had for a long time been incapable of exercise and subject to oppression of breathing and cough. The patient was seen as he was recovering from an apoplectic attack which had seized him three days previously. At this time he was able to go about the house but was still oppressed by stupor, a constant disposition to sleep, and troublesome cough. Adams says: "What most attracted my attention was the irregularity of his breathing and the remarkable slowness of the pulse, which generally ranged at the rate of 30 a minute." The patient's medical attendant, Mr. Duggan, gave Adams the following history. "The patient had had at least 20 apoplectic attacks in the last seven years, preceded for a day or two by vertigo and loss of memory. During the fits the pulse would become even slower than usual." (No statement as to the frequency is given here.) Death occurred in a fit six months after he was first seen by Adams. At the necropsy fatty degeneration of the heart was found. In his comments on the case Adams says: "When the heart is slow in transmitting the blood it receives we find, I imagine, even in this a means of accounting for the lethargy, loss of memory, and vertigo which attend these cases"

The next reference to this disease appears to have been by W. Stokes,[2] where he published a paper on Observations on Some Cases of Permanently Slow Pulse. The first case was thus described. "*Repeated pseudo apoplectic attacks not followed by paralysis; slow pulse, with valvular murmur.*—A had a fainting fit three years previously and

lump in the stomach, 'passing up through the right side of the neck into the head where it seems to explode and pass away with a loud noise resembling thunder, by which he is stupefied.' This is often accompanied by a fluttering sensation of the heart. No convulsions or frothing at the mouth during the fit, but he has occasionally injured his tongue. Fit seldom lasts more than four or five minutes During the fit the patient is entirely unconscious; but he has no paralysis after any fit. He never heard that his pulse or heart was affected He had found that spirits were the best restoratives but he had not used them latterly, being 'afraid to die with spirits in his belly.' He always feels cold unless he is near the fire On admission there was slight cough and expectoration, and large mucous râles over the lungs The heart's impulse was slow, dull, prolonged, and heaving, giving the idea of painful as well as slow action. The first sound was accompanied by a blowing murmur heard very distinctly up along the sternum and even into the carotid arteries; second sound also imperfect, though very slightly so. Pulse 28, prolonged, and sluggish Arteries pulsate visibly all over the body and appear to be in a state of permanent distention. Urine sp. gr. 1010; free from albumin" The pulse varied from 28 to 30, at times rising to 36 The patient had two threatenings of a fit after admission but the attacks were warded off by turning on his hands and knees and keeping his head low. This often averts a fit Stokes says that occasionally "some of the beats" occurred between the regular contractions unattended with impulse or pulse. Stokes did not observe any of the fits himself and the patient had no fits after admission. He was discharged improved and was lost sight of.

Stokes described briefly another case which was summarised thus: "Anæmia, very slow pulse, valvular murmur, death apparently from syncope. Post mortem, aortic stenosis was found." No further details A third case was communicated to Stokes by Dr. Law. The patient, a man, aged 44 years, had a pulse of from 24 to 30 and suffered from apoplectic attacks, in one of which he died. No necropsy was made.

---

[1] Vol iv., p. 396.

[2] Dublin Quarterly Journal of Medical Science, 1846.

Very little attention seems to have been directed to this disease subsequently, as shown by the fact that the late Dr. J. S. Bristowe in his presidential address to the Medical Society of London in October, 1893, On the Influence of Extreme Slowness of Pulse in the Causation of Epileptiform Convulsions,[3] stated that the earliest recorded case was published in THE LANCET of 1885 by Mr. F. St. George Mivart.[4] A man, aged 61 years, had been subject to epileptic seizures for six years and the pulse varied from 20 to 26. There were a slight systolic murmur at the base and a prolonged first sound at the apex. The urine contained a trace of albumin. Mr. Mivart regarded these symptoms as "simple slowness modified by the patient's epileptic tendency." The next case Dr. Bristowe mentions is to be found in THE LANCET of the same year by Dr. A. T. Gibbings.[5] The patient, a man, aged 66 years, stated that his pulse had been intermittent as long as he could remember. He was first seen in 1882, suffering from weakness, dyspnœa on exertion and occurring spontaneously at night, and cough. The pulse was 60 and intermittent and the heart was free from murmur. Ten months later the pulse was 44 but regular. Subsequently dyspnœa and faintness appeared and the pulse fell to 34. Consultations were held with Sir Andrew Clark and with Dr. Walter Moxon. Fainting and epileptiform attacks recurred. During each attack the pulse became very slow, at times falling to 12 Towards the end it varied from 15 to 31. The first indication of an attack was the non-occurrence of the usual pulse beat. The patient died in a fainting fit ten months after he was first seen. A post mortem examination in the presence of Dr. Moxon showed that the heart and other organs were all healthy. Dr. Gibbings attributed the epileptiform seizures to anæmia of the brain and suggested that the slow action of the heart was due to an irritative lesion of the vagus or degeneration of the cardiac ganglia.

The next case was recorded by Dr. Bristowe also in THE LANCET of the same year.[6] A man, aged 31 years formerly a soldier, had had syphilis, fever, and ague in India. He was discharged after 12 years' service for "weakness of the constitution." He had never had rheumatism nor had he suffered previously from dyspnœa Two weeks before admission into St. Thomas's Hospital he had an attack of faintness after mental excitement and the next morning he had heavy breathing. On the following evening he had shortness of breath and he lost consciousness. Since then similar attacks had recurred frequently, both night and day. The fits were preceded by faintness and followed by flushings and insensibility. He once bit his tongue. There was no pain in the chest. During his stay in the hospital fits occurred frequently and seemed to come on always after long periods of cardiac intermission, the pulse rate being 26 or slightly more as a rule. When intermission was prolonged to five seconds a fit generally followed. A loud, roaring, systolic murmur was heard above and to the right of the apex of the heart and was prolonged to the base. The fits recurred frequently. Their duration varied much but unconsciousness only lasted a few seconds. The pulse became more frequent, rising once to 80, sometimes regular, at other times very irregular. The patient lost his palpitation, dyspnœa, and fits and was discharged and lost sight of.

The fourth case was seen by Dr. Bristowe with Dr. John C. Ferrier. A widow, aged 54 years, had had acute rheumatism, followed by cardiac uneasineas one year previously. In September, 1891, she had an attack of giddiness,,and similar attacks followed in which she lost consciousness. The attacks lasted a few seconds and were attended with pallor, a cessation of respiration, unconsciousness, and slight convulsions. During the attack the pulse was about 30. The attacks became more frequent and the pulse fell to 17. The urine became slightly albuminous. On the day before death the pulse became regular, from 108 to 120, but then it fell to 20 and later to 18. Occasionally a soft systolic murmur was heard at the apex, but nothing further was detected. Death occurred quietly about three months after the first fit and was preceded by a disappearance of fits for the last three and a half hours.

The fifth case was not seen by Dr. Bristowe during life but the history was obtained subsequently to the postmortem examination. The patient had had fits off and on for about two years. On admission the pulse varied from 25 to 30, the cardiac dulness was abolished, the first sound at the apex was blowing, and the sounds at the base were weak. The pulse at times rose to 72 The fits came on when the pulse became very infrequent (from 20 to 25), but not invariably. Death occurred in a fit one month after admission. At the post-mortem examination the heart weighed 15¼ ounces. The left ventricle was hypertrophied, but not dilated. There was slight atheroma of the aorta and coronary arteries and of the mitral and aortic valves. Big toe-joints contained urate of soda.

Although this affection received little attention in England after Stokes's paper above referred to continental and American authors were well aware of its existence. Huchard in his work on cardiac disease speaks of it as the "Stokes-Adams syndrome." He regards the slow pulse as the result of changes in the vagus centre due to arterial disease and describes the affection as "the cardio-bulbar form of arterio-sclerosis." He mentions the fact that Stackler and Lannois each published a case of permanently slow pulse with syncopal attacks due to compression of the vagus nerve. Dr. W. Osler in his lectures on "Angina Pectoris and Allied States" in 1897 refers to this disease which he regards as having close connexion with angina. Dr. Osler considers that transient disturbances of the cerebral circulation are responsible for the syncope and apoplectiform attacks which remind one of the transient hemiplegia, monoplegia, aphasia, and paraplegia to which the subjects of advanced arterio-sclerosis are liable. He mentions a case fully described by Prentis of Washington of a man, aged 53 years, the subject of arterio-sclerosis who had innumerable fainting spells and a slow pulse which for two years varied from 11 to 40. The patient was delirious for some days before his death. At the post-mortem examination the heart was enlarged but there was no atheroma of the aorta or coronary arteries. Sections of the medulla oblongata showed congestion only.

Dr. Osler describes one case himself. A man, aged 46 years, who had never had rheumatism, chorea, or syphilis, had not been alcoholic, and had not been subjected to hard labour, complained of præcordial uneasiness on waking which had been coming on for two years. The patient could not lie flat on his back but could lie on either side with his head raised. There was no sharp pain in the chest but he had an uneasy sensation and a feeling of suffocation. There was no agonising sensation or palpitation. At times severe vertigo was present but not loss of consciousness. A year previously he noticed that his pulse was very slow and in the early morning it had been as low as 20 per minute. When seen by Dr. Osler his pulse was 34, the tension was increased, the up-stroke was laboured, and the wave was well sustained. Cardiac dulness was normal, impulse was not visible, and there was no abnormal pulsation. Hypertrophy was not evident. There was a systolic murmur at the aortic cartilage but no accentuation of the aortic or pulmonary second sound. The patient was relieved somewhat as regards the vertigo but his slow pulse persisted.

Huchard gives a useful classification of "bradycardia" as follows: (1) physiological (an idiosyncrasy seen in some healthy persons, for instance, Napoleon, whose pulse was said to be 44); (2) convalescence from typhoid fever, pneumonia, and other acute diseases; (3) toxic (digitalis, aconite, colchicum, opium, tobacco, tea, coffee, and uræmia); (4) reflex from the digestive organs; (5) nervous (meningitis, insanity, melancholia, neurasthenia, hysteria, epilepsy, cerebral disturbances of various sorts, lesions of the spinal cord and vagus trunks); and (6) cardiac (fatty heart, aortic stenosis, coronary sclerosis, and cardio-bulbar arterio-sclerosis).

Robert Adams who first described this affection clearly regarded the slow action of the heart as the primary factor This view was more precisely stated by Dr. Gibbings Huchard boldly stamps the complaint as the cardio bulbar form of arterio-sclerosis. Dr. Osler is more cautious and would explain the syncope and other cerebral symptoms as the result of transient disturbances of the cerebral circulation analogous to the temporary paralyses that occur in arterio-sclerosis. Cases like those of Gibbings and Prentis make one hesitate to accept Huchard's view that the affection is due to organic disease of the bulbar arteries as universally true. The cases that have been described illustrate the fact pointed out by Osler that slowness of the heart's action may cause different grades of cerebral disorder, vertigo, syncope, or epileptiform attacks. The case that I have brought forward is an instance of the severest form and it is interesting to note the length of time during which in two attacks the pulse disappeared at the wrist—viz., 40 and 90 seconds. Unfortunately the heart was not examined during this period. But I repeatedly examined the heart myself when the pulse was 30 and I always found that the pulse and heart sounds exactly corresponded. This patient shows no sign of general arterial degeneration though lesions of the coronary arteries cannot be excluded. It is probable that she is suffering from aortic stenosis.

THE SIGNIFICANCE OF THE ZOOLOGICAL DISTRIBUTION, THE NATURE OF THE MITOSES, AND THE TRANSMISSIBILITY OF CANCER.[1]

BY E. F. BASHFORD, M.D. EDIN.,
GENERAL SUPERINTENDENT AND DIRECTOR, CENTRAL LABORATORY OF CANCER RESEARCH FUND OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND;
AND
J. A. MURRAY, M.B., B.SC. EDIN.

[We are informed by the assistant-secretary and librarian of the Royal Society that excepting the summary which was sent to the "Times" the day after the paper was read any version which has already appeared in the press is an unauthorised version. We received permission to publish the paper on Monday last, Feb. 8th.—Ed. L.]

THE object of this communication is to relate some results of the work conducted under the immediate direction of the executive committee of the Cancer Research Fund during the past year. We believe that these results will convince others of the important practical assistance which biologists generally can give in the further elucidation of certain problems of cancer which must be settled before scientific preventive and curative measures can be devised. It will also be made evident that the elucidation of cancer is something more than a problem of human pathology only. We shall adduce evidence tending to show that the wide zoological distribution, the character of the mitoses and the transmissibility of cancer are nearly related phenomena with a common basis. The fundamental significance of ascertaining the extent of the zoological distribution of cancer was recognised by the Cancer Research Fund from the first and determined the prosecution of definite lines of inquiry with all the means at the disposal of the organisation, not only with the object of eliciting new facts in regard to the zoological distribution itself, but also with the object of discovering cancer in animals well adapted to cytological and experimental observations.

Zoological Distribution.

Within the past year specimens of malignant new growths have accumulated from all the domesticated animals and from many other vertebrates. The appended list shows the abundance of the material which has thus been examined. The list includes also specimens which we have been privileged to examine through the courtesy of investigators abroad, who, subsequently to the inauguration of the Cancer Research Fund, have published descriptions of malignant tumours in the lower vertebrates. It is noteworthy that such growths have been obtained not only in domestic animals but also in animals living in a state of nature—wild mouse, codfish, gurnard. The clinical, pathological, anatomical, and microscopical characters of these new growths are identical with those found in man in all essential features, although the animals themselves are drawn from the different classes of the vertebrate phylum. A detailed histological description of the various tumours examined will not be attempted here. Only the general significance of the observations in relation to the incidence of cancer in man will be emphasised.

The great diversity of the habitat, food, and conditions of life generally of the forms in which malignant new growths occur relegates such external conditions to a subsidiary rôle in determining the incidence of the disease and shows that the essential factors must be sought in the potentialities which reside in the cells constituting the living body. The list of specimens, while giving no safe basis of deduction as to the relative incidence of cancer in the different classes of vertebrates, or of the comparative susceptibility of the different sites of the body, is extremely suggestive. The large number of epitheliomata obtained in the horse and dog indicates very clearly that malignant new growths are recognised according to the ease with which animals can be examined and the length of time they are kept under observation. The larger ratio of malignant new growths occurring in the internal organs of cows have been discovered during meat inspection at abattoirs and form a welcome corollary to the other observations. Stated generally, it may be said that malignant new growths are frequent according as animals are carefully examined, and are unrecorded in forms which are difficult to examine or do not reach old age in considerable numbers. The figures are not sufficiently extensive to determine accurately the age incidence of the various types of new growths in different animals, but a relatively higher incidence in old age is apparent.

The Phenomena of Cell-division in Malignant New Growths.

The progressive increase in size of malignant tumours is due to the division and increase in size of their constituent cells The process of cell-division is usually indirect, mitotic division of the nuclei preceding the division of the protoplasm. The protoplasm division is frequently omitted and multi-nucleated cells are formed and these may subsequently enter on mitosis, giving rise to pluripolar figures. Amitosis or direct nuclear division also occurs, but its full significance has not yet been determined. It is, however, evident that the occurrence of amitosis does not signify degeneration. The amount of chromatin entering into the equatorial plate of the mitoses of malignant new growths had long been recognised as subject to variation (hyperchromatosis, hypochromatosis of von Hansemann, 1893), but a new light has been thrown on this phenomenon by a paper communicated to the Royal Society on Dec. 10th, 1903, by J. B. Farmer, F.R.S., J. E. S. Moore, F.L.S., and C. E. Walker, entitled "Resemblances exhibited between the Cells of Malignant Growth in Man and those of Normal Reproductive Tissues." These observers found that while the growing margin of carcinomata and sarcomata presented mitoses similar to those found in other tissues in repair and inflammation, certain cells in the deeper layers, after a slight increase in size, entered on mitosis with ring chromosomes similar to those found in the heterotype division of spore-mother cells of plants and spermatocytes of animals, and like these, with chromosomes in number only half that characteristic of the mitoses of somatic cells. Mitoses similar in character to the somatic divisions but with reduced number of chromosomes were also seen (homotype) corresponding to the divisions in the sexual generation of plants and the second ripening divisions of animals. From these observations the authors concluded that malignant new growths were virtually reproductive tissue arising in abnormal situations and possessed of an independence and power of growth like that of the testis in the mammalian body.

This striking sequence of characteristic mitoses had been found in all malignant tumours examined and was absent in those of benign character. We at once determined to communicate with the authors who with great courtesy afforded us an early opportunity to examine their preparations. It was then decided to determine how far similar phenomena were characteristic of the malignant new growths occurring in animals. The result has been a complete confirmation of Farmer, Moore, and Walker's observations in tumours from the trout (Mr. Gilruth's and Miss Plehn's cases of adeno-carcinoma), the mouse (two cases of adeno-carcinoma, Jensen's epithelioma), and the dog (mixed cell sarcoma, round cell sarcoma, squamous cell carcinoma). In the columnar cell carcinoma of the trout the phenomena were especially distinct, the small number of chromosomes[2] (24,

[1] A paper communicated to the Royal Society by Dr. J. Rose Bradford, F.R.S.

[2] The achromatic figure has always been carefully studied as a control to the observations made on the chromatin of the mitosis. When the chromosomes have been counted, this has been done on sections 5—10 μ thick, mounted in series.

ILLUSTRATION OF THE THREE TYPES OF CHARACTERISTIC MITOSES IN ADENO-CARCINOMA.

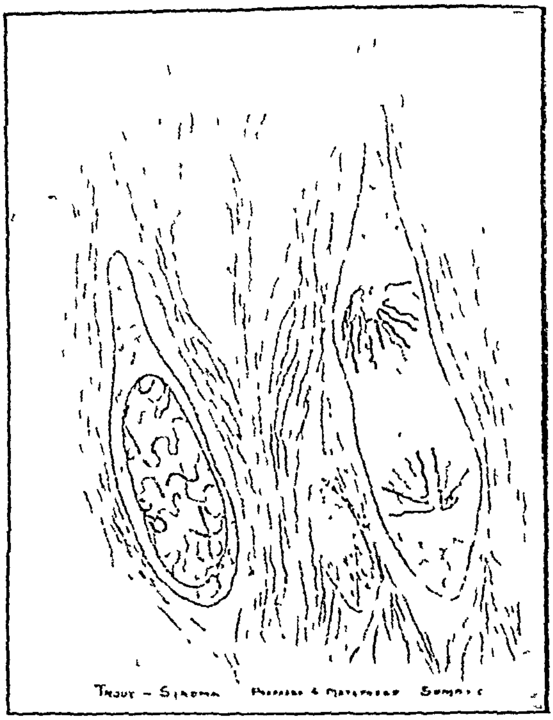

FIG. 1.—The chromosomes in the stroma mitoses are long, slender, V-shaped loops which split longitudinally, 24 in number. They are somatic in type; cf. Fig. 2 from the tumour.

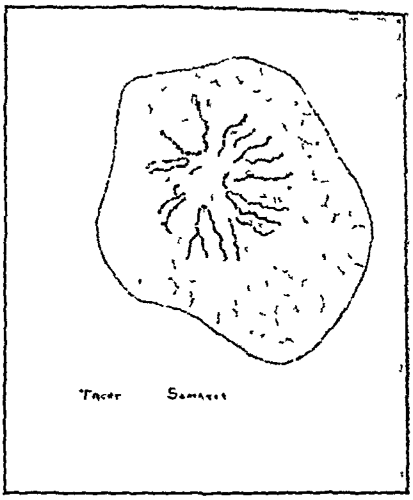

FIG. 2.—Somatic equatorial plate in margin of tumour seen from the pole. Slender V-shaped chromosomes, 24 in number, arranged transversely on the spindle showing longitudinal splitting. All the chromosomes are not reproduced in the figure.

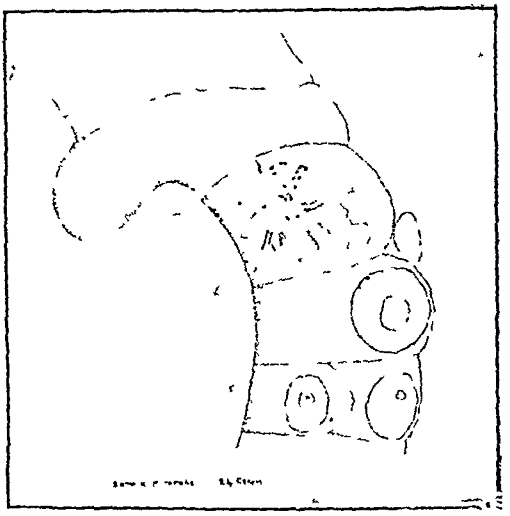

FIG. 3—Somatic metaphase, polar view. The angles of the V-shaped daughter chromosomes are directed upwards towards the observer and appear as two dots on deeper focussing 24 chromosomes. (Illustrates method of counting chromosomes and is not included in the Royal Society's reproductions.)

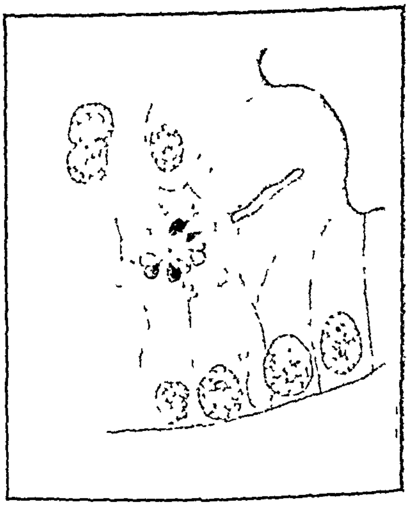

FIG. 4—Heterotype mitosis seen from pole chromosomes present i reduced number (12) and in the form of short thickened rin (vide Fig. 5). All the chromosomes are not reproduced in th figure.

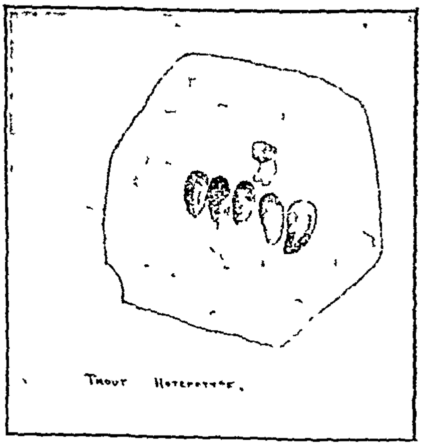

FIG. 5—Heterotype mitosis seen from side Ring chromosomes in reduced number, arranged lengthwise on the spindle.

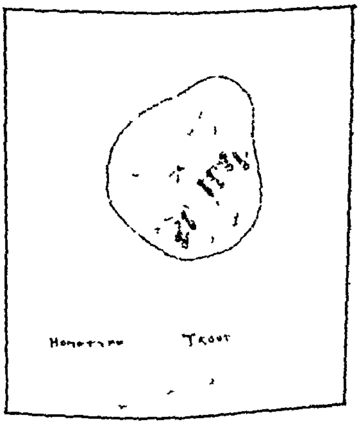

FIG. 6—Homotype mitosis Longitudinal split chromosomes arra transversely on the spindle. *Reduced* number as in hetero (12). All the chromosomes are not reproduced in the figure.

[illegible] the long slender chromo-
be rings of the heterotype
clearness. Homotype mitoses occurred but were very few in number. Mitoses in the stroma are relatively scanty in the tumours at our disposal, but such as have been seen are somatic in character. Farmer, Moore, and Walker record a similar result. In the mouse it has been possible to compare the mitoses in the testis and those occurring in the irritation produced by iodine, with the result that the significance of the mitoses in cancer has been further confirmed.

The following points are of great importance in these observations. A complicated sequence of cell-changes has been found to be characteristic of carcinoma and sarcoma alike. This sequence is the same as that which initiates the origin of the sexual generation in plants from the asexual and is terminal in the history of the sexual cells in animals. It must be noted also that all the cells of the malignant new growths do not undergo the reducing division, a certain number differentiate in the direction of the tissue among which they have arisen, and in the secondary growths when present somatic mitoses occur in the growing margin, which it will subsequently be shown is also a feature in the growth of cancer when transferred to a new host.

The Transmissibility of Malignant New Growths from one Animal to Another.

The transmission of cancer from man to animals, or from one animal to another of different species, has never been successfully performed. Successful transplantation experiments have been made, however, from animals suffering from malignant new growths to others of the same species. The most exhaustive observations in this connexion have been made by Jensen and Borrel on mice. Professor C. O Jensen of Copenhagen most generously placed at the disposal of the Cancer Research Fund a portion of one of his experimental tumours,[3] and with this and another tumour occurring naturally in a tame mouse similar experiments have been performed. We have thus been able to confirm Jensen's observations by microscopical examination of the tissues at the site of inoculation at short intervals and have found that the new tumours which develop arise from the actual cells introduced. While many of these degenerate a few remain of normal appearance and these gradually increase in number. In the earliest transplanations mitotic division is absent and it is not till later, when a considerable mass has arisen, that mitoses appear. The earliest mitoses we have been able to observe have been of the somatic type. Transplantation is, in fact, identical with the process of metastasis as it occurs in the individual providing the tumour. It is remarkable, however, that the tumour of Jensen's experiments does not produce metastases naturally and its malignancy is only evidenced by its progressive growth and the undifferentiated character of the cells. The process is in no sense an infection, the tissues of the new host not participating in the formation of the new parenchyma. In this interpretation we are in agreement with Jensen and differ from Borrel who conceives the results to be due to the agency of a *virus cancéreuse*.

The origin of the stroma has not been accurately determined. The power of growth of this tumour is remarkable. In every mouse in which the transplantation succeeds the new growth may attain a weight equal to that of the animal itself, and over 400 such transmissions have been effected by Jensen in Copenhagen and the Cancer Research Fund in London. A mass of tumour, 16 pounds in weight, has thus actually arisen from the original one, and that without participation of the cells of the various hosts and without manifest change in structure. This great power of growth is a phenomenon unparalleled in the mammalia and indicates the potentialities in cases in which widespread dissemination has occurred before death in a human patient.

The experimental transmission of carcinoma shows that we must distinguish between the problem of the genesis of a malignant new growth and that of the conditions which permit of [illegible]
While the conditions lead-
t tumours are relatively in-
[illegible] wards of 1000 tame mice and have discovered two with cancer; once begun, this proliferative activity can persist, given favourable conditions, for a long time unaltered and can give rise to masses of tissue of great size, having no relation to the restrictions which

limit the growth of adult organisms in a large proportion of healthy animals. The phenomena of cell division, indicating a similarity to the normal reproductive tissues, may help to explain the nature of this great power of multiplication but leave the problem of cancer genesis practically untouched. They give, however, important indications of the character of the processes on whose elucidation the solution of the question depends. The wide zoological distribution of malignant new growths—its limits are not yet determined—indicates that the cause of cancer is to be sought in a disturbance of those phenomena of reproduction and cell life which are common to the forms in which it occurs. Our observations on animals show that malignant new growths are always local in origin and of themselves produce no evident constitutional disturbances whatsoever. These facts are in full accord with accumulated clinical experience in man. In connexion with diagnosis and statistics we have already emphasised the importance of the absence of specific symptoms. The evidence we have advanced that cancer is an irregular and localised manifestation of a process otherwise natural to the life cycle of all organisms probably explains why it is that malignant new growths, and their extensive secondary deposits *quâ* cancer, are devoid of a specific symptomatology.

[We desire to add the accompanying dated note because we find that conclusions which have been drawn by others are attributed to us.

Note.—We find that the guarded terms in which the points of importance are emphasised may lead to a misconception of our interpretation of the facts. The cells which have undergone the reducing division are not responsible for the active invasion of surrounding tissues nor for the production of metastases; the cells dividing somatically are responsible for both. The number of heterotype mitoses may not stand in any relation to the degree of malignancy, and their absence is only presumptive evidence of the benign character of the tumour. We postulate nothing as to the future of the cells which have undergone the reducing division, though we believe the latter to be a terminal phase in the life-cycle of cancer cells as it is in the history of sexual cells in animals. The local origin and the expansive and infiltrating growth of cancer in its relation to surrounding tissues, while respecting its own proper elements, is the criterion of its malignancy. This stamps it as belonging to a new cycle comparable in its entirety to the whole organism which it is invading rather than to any one of its tissues, reproductive or otherwise. We intentionally restricted our original statement to recording the facts and only such general conclusions as could be irrefutably drawn from them.—Jan. 25th, 1904.]

We cannot here make full acknowledgment to those who have assisted our inquiry in this country but our indebtedness may be expressed to those observers abroad who have recorded isolated instances of cancer in animals and have so generously furthered our investigations by placing material or specimens at our disposal. In particular we desire to thank Professor Borrel of the Pasteur Institute, Professor C. O. Jensen of Copenhagen, Mr. J. A. Gilruth, chief of the Veterinary Department, New Zealand, Professor Landau and Dr. L. Pick of Berlin, and Dr. Marianne Plehn of Munich. Without the generous coöperation of these and many others it would not have been possible within so short a time to have covered the extensive ground indicated in this paper.

THE ETIOLOGY AND TREATMENT OF SUPPURATION OF THE LABYRINTH.[1]

By WILLIAM MILLIGAN, M.D. Aberd.,
LECTURER ON DISEASES OF THE EAR AT THE OWENS COLLEGE, MANCHESTER.

Septic disease of the labyrinth demands our most careful consideration in the first place on account of the damage which may be done to the acoustic or to the static segments of the internal ear and, in the second place, on account of the risk which exists of the pathogenic process extending to the basal meninges or to the adjacent lobes of the cerebellum. The most frequent causes of infection of the internal ear are: (1) suppurative lesions of the middle ear extending through the external labyrinthine wall; (2) suppurative processes originating at the base of the brain and extending along the perivascular or perineural sheaths of the auditory or facial nerves; (3) deposition of pathogenic organisms by the general blood stream in some portion of the internal ear; and (4) injuries. The most frequent, and from the practical point of view the most important, cause is extension from the cavity of the middle ear. In the great majority of cases due to this particular cause perforation into the labyrinth has taken place either as the result of erosion of the bony labyrinthine wall or as the result of maceration of the fibrous structures uniting the foot-plate of the stapes to the margins of the foramen ovale or of the membrana secundaria covering the fenestra rotunda.

Perforations leading into the cavity of the internal ear may also be of traumatic origin as in cases of fracture of the base of the skull, direct injuries—e.g., foreign bodies introduced into the meatus—or as the result of operative interference, the labyrinth being opened either intentionally or accidentally. The virulence of the infection and its exact exciting cause determine to some extent at least the nature, extent, and behaviour of the resulting inflammatory process. In cases which run a slow and almost painless course a cario-necrotic process is induced which may result in the whole or considerable portions of the labyrinth being exfoliated in the form of sequestra. In such cases the disintegrating process is frequently of a tuberculous nature. In other cases, however, the infective process may be so acute as to lead to the rapid transference of infective organisms along the perivascular or perineural sheaths of the auditory or facial nerves to the base of the brain.

The frequency of labyrinthine suppuration is difficult to gauge, partly because in most clinics sufficiently detailed statistics are but rarely kept and partly because the attention of the profession has not as yet become sufficiently focussed upon this particular complication of middle-ear disease as a factor in the production of high degrees of deafness and of intracranial involvement.

The route of most frequent infection from the middle to the internal ear is through a fistulous tract in the horizontal semicircular canal and the second most important pathway is through the fenestra ovalis. In a recent paper by Victor Hinsberg out of 198 cases of labyrinthine suppuration collected by him from various sources the pathway of infection was definitely established in over 60 cases. In 27 a fistula was found in the horizontal semicircular canal, in 17 the infective organisms had entered the internal ear by way of the fenestra ovalis, in two by way of the fenestra rotunda, in three through both windows, in seven a fistula was found in the pars promontoria, and in eight through the posterior or superior semicircular canal.

Labyrinthine suppuration is rare as the result of acute

---

[1] A paper read before the Otological Society of the United Kingdom on Feb. 1st, 1904.

middle-ear sepsis and for precisely the same reasons as intracranial complications are comparatively uncommon after acute suppurative otitis media. Considerable time is required [illegible] cro-organisms is able to [illegible] the labyrinth or the com- [illegible] ch close in the fenestræ. The precise point of invasion and the virulence of the pathogenic process determine the particular segment of the internal ear which is involved and the extent of the involvement. In 18 cases out of a total of 89 collected by Hinsberg the labyrinthine involvement was due to acute otitis media; in 71 to chronic disease. In 21 of the 71 cases following chronic suppurative otitis media cholesteatomata were present. In some cases the septic process becomes localised to the region of the semicircular canals, to the vestibule, or to the cochlea. Usually, however, the contiguity of these various segments determines their almost simultaneous infection. Circumscribed necrosis most usually affects the external lamella of the pars promontoria which is thrown off in the form of a thin plate of bone. Occasionally the whole or a considerable portion of the cochlea may come away as a sequestrum. In other cases portions of the semicircular canals become detached and exfoliated. The accompanying illustrations (Figs. 1, 2, and 3) show a [illegible] canals removed [illegible] suffered from [illegible] 20 years and [illegible] ital had been [illegible] vertigo, and profound deafness upon the affected side. A radical mastoid operation was performed and extended into the labyrinth

FIG. 1.

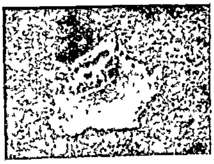
where the se[illegible] tissue. Aft[illegible] and local [illegible] tuberculous [illegible] of the external labyrinthine wall is frequently invaded. Of 33 cases of labyrinthine tuberculosis collected by Barnick both fenestræ were found perforated in five cases, the oval window alone in two, and the round window alone in three.

When the inflammatory process remain circumscribed the round celled infiltration which takes place becomes ultimately organised with the result that the spaces existing in the internal ear become filled up by a dense fibrous tissue which ultimately becomes ossified. Once the labyrinth has become the site of purulent invasion the risks of extension to the base of the brain are obvious. The normal pathways which exist between the internal ear and the basal meninges are the tracts along which pathogenic organisms travel. In the great majority of cases infection from the labyrinth attacks structures within the posterior fossa. A few cases, however, are on record where the pathological process has caused carious erosion of the anterior crus of the superior semicircular canal with the result that the middle cranial fossa becomes opened up and infected. Most usually the resulting intracranial infection takes the form of a diffuse suppurative pia-arachnitis. Occasionally it remains as a localised process—e.g., an extradural abscess in the posterior fossa or over the tegmen tympani in the middle fossa. The contiguous portions of the lateral lobe of the cerebellum are also prone to become infected. [illegible] from 20 to 30 per cen[illegible] in practice are due to labyrinthine infection.

FIG. 3.



Sequestrum consisting of portion of cochlea from case of labyrinthine suppuration.

Septic invasion of the labyrinth may run an acute or a chronic course. When acute, certain striking symptoms present themselves. Thus deep seated boring pain is complained of, there are a rapid elevation of temperature and other febrile indications, sickness or nausea is almost invariable, and vertigo is so pronounced as to necessitate the patient's remaining in the horizontal position. Nystagmus either in the vertical or in the horizontal plane is common, whilst rapid and at times complete nerve deafness is almost invariable. In the more usual class of case, however, the invasion of the labyrinth runs an almost chronic course, the external labyrinthine wall slowly crumbling away as the result of repeated micro-organismal attacks. In such cases symptoms, although fairly characteristic, are not nearly so well marked as in acute infections. Pain is frequently absent, vertigo is not so pronounced, often being more of the nature of a swimming sensation in the head, there is slight if any elevation of temperature, and sickness is by no means constant. The existence of these symptoms combined with a rapid onset of nerve deafness and the frequent presence of nystagmus should at once attract attention to the probability of the internal ear being affected. Another important symptom is the presence of facial paresis or paralysis. Facial paralysis supervening in the course of a chronic suppuration of the middle ear is always a signal of the presence of deep-seated disease. Too often, I think, it is regarded as an indication of middle-ear disease. I am satisfied from clinical and from post-mortem experience that its onset frequently indicates a labyrinthine lesion, the nerve being implicated in its passage through the pars petrosa and before it has reached the cavum tympani. In exceptional cases where the process is localised the symptoms will depend upon the particular portion of the internal ear which is involved—viz., the static or the acoustic segments. Where the cochlea is involved symptoms referable to disease of the terminal filaments of the auditory nerve will be present. Thus tinnitus is always complained of, whilst a varying amount of loss of perception for high tones will be met with according to the extent and situation of the existing lesion. In the great majority of cochlear lesions high degrees of deafness are found. Should the suppurative process, however, be confined to the region of the semicircular canals or vestibule the predominant symptoms will be vertigo, nystagmus, and intermittent attacks of nausea or actual sickness. In 57 out of 97 cases of uncomplicated fistula of the horizontal semicircular canal Jansen found marked vertigo to be present, whilst Lucae in 30 out of his 50 cases found the same conditions prevailing.

In localised suppuration of the semicircular canals or vestibule a fair degree of hearing may exist. The occurrence of rapidly advancing nerve deafness in a case of chronic suppurative disease of the middle ear should at once direct attention to the probability of labyrinthine involvement. If accompanied by vertigo, attacks of sickness, nystagmus, and constant tinnitus, the diagnosis is, of course, rendered somewhat easier although the possibility of a concomitant lesion of the cerebellum must not be lost sight of. In actual practice we have to deal with cases where the lesion secondary to the middle-ear infection is confined to the labyrinth, probably a much more frequent condition of affairs than is usually supposed, where it is confined to the cerebellum and where both a labyrinthine and a cerebellar lesion coexist. An accurate differential diagnosis is at times a problem of the utmost difficulty, the symptoms being in many cases so similar.

In uncomplicated labyrinthine suppuration without any intracranial lesion greater degrees of nerve deafness are usually present, vertigo is more of the nature of the subjective sensation of extreme dizziness than of that form of staggering gait known as the cerebellar gait, sickness and prostration are less marked, occipital pain and retraction of the head are absent, optic neuritis, which is present in about 70 per cent. of the cases of cerebellar abscess, is also absent, whilst the dull and somnolent condition of the patient is more suggestive of a cerebellar than of a labyrinthine lesion. In addition the peculiar coiled-up position of the patient when lying in bed and the occasional existence of motor paresis or paralysis of the same side of the body are highly suggestive of a cerebellar abscess. Nystagmus is comparatively common in labyrinthine suppuration. Jansen and Lucae found it present in all their cases of traumatic perforations. Jansen also found it present in 24 out of 97 cases of carious perforation—practically 25 per cent.—whilst Lucae found it present in 31 per cent. of his cases of fistula of the external semicircular canal.

The coexistence of cerebellar abscess with labyrinthine suppuration, although by no means uncommon, is extremely difficult of diagnosis and is frequently only found out in the course of operative procedures or as the result of the after history of the case. The following notes present a typical picture of an uncomplicated case of labyrinthine suppuration.

CASE 1.—The patient, a male, aged 29 years, had suffered for 11 years from profuse discharge from his left middle ear following a severe attack of scarlet fever. The discharge was fœtid and blood-stained. The hearing power had for long been much impaired and had become rapidly worse a few weeks prior to the patient being seen in consultation. Severe vertigo was complained of and on two occasions vomiting had occurred quite suddenly and quite independently of the partaking of food. No definite pain either in the ear or in the head was complained of but the patient felt ill and was quite unable to follow his usual occupation. When first seen the following notes were made: "Patient pale and anæmic, tongue thickly furred, bowels constipated, temperature 97·8° F., pulse 70. Left auditory meatus blocked by a large œdematous polypus in a bath of putrid pus. Bare bone felt by means of a probe in the depths of the meatus. Hearing upon affected side one-sixtieth of the normal Tuning-fork tests show want of perception for high tones; no nystagmus; no optic neuritis." Under chloroform anæsthesia a complete radical mastoid operation was performed and a careful toilet of the external labyrinthine wall was made. The stapes was found imbedded in granulation tissue and when gently grasped with a pair of forceps at once came away. Succulent granulation tissue was seen to fill the vestibular cavity. By means of a small burr the fenestra ovalis was carefully enlarged and a quantity of disorganised tissue was removed from the vestibule. Either during the enlargement of the fenestra ovalis or during the subsequent process of curetting the facial nerve was injured and for a short time after operation facial paresis existed. This, however, ultimately entirely cleared up. The cavity thus made in the labyrinth was lightly packed and the subsequent treatment of the radical mastoid operation was carried out upon recognised principles. The patient made a good, although slow, recovery and is now at work as usual. All vertiginous symptoms disappeared after the operation. He is, however, completely deaf upon the affected side.

To illustrate the practical difficulties encountered in making an accurate diagnosis where labyrinthine and cerebellar suppuration coexist the following case, which was diagnosed as one of labyrinthine suppuration, may be cited. Unfortunately the possibility of a coexisting cerebellar abscess was not entertained at the moment. Four days after the labyrinthine operation, however, a cerebellar abscess was opened but with an unsuccessful result.

CASE 2.—The patient, a male, aged 33 years, was admitted to hospital complaining of deep-seated pain in his left ear, marked vertigo, and constant nausea. Examination showed chronic left-sided purulent otitis media, deep-seated caries, bone granulations, and severe nerve deafness upon the affected side. The temperature on admission was 102° F., the pulse was 64, and the respirations were 20. For three or four days prior to admission the patient had complained of severe dizziness and on two or three occasions he had been sick. A diagnosis of labyrinthine suppuration was made. Under an anæsthetic a complete radical operation was performed, the facial spur being freely removed so as to gain a good view of the external labyrinthine wall. A fistula was at once seen in the region of the horizontal semicircular canal leading into the internal ear. A small sequestrum was scooped out and some succulent granulation tissue was removed with the curette. The after-treatment was conducted upon ordinary principles. The patient did not, however, rally from the operation as was expected. The temperature became subnormal (96·4°) and he sank into a dull, listless, and apathetic mental condition. Occipital pain increased slightly and one or two attacks of vomiting during the two days subsequent to the operation made it evident that some other complication existed. It was accordingly decided to explore the adjacent portion of the cerebellum. Four days after the first or labyrinthine operation the cerebellum was opened and an abscess occupying the anterior portion of the left lateral lobe was at once found. After evacuation of pus and a few shreds of disorganised brain tissue a drainage tube was inserted. The patient, however, did not rally and he died on the following day. Unfortunately, a post-mortem examination could not be obtained.

In this case had a correct diagnosis of labyrinthine plus cerebellar suppuration been made and had both purulent foci been evacuated at the same time the result might have been different. On the other hand, the symptoms of labyrinthine suppuration may so resemble symptoms of cerebellar abscess as to lead to the diagnosis of a mixed lesion when the labyrinth is the part alone involved. The fact also that in suppurative labyrinthitis the amount of cerebro-spinal fluid is increased with a corresponding increase of intracranial tension, as evidenced by depression of the various vital centres, slow pulse, subnormal temperature, and slow respiratory movements, tends materially to increase the difficulties of differential diagnosis. The following case illustrates this point.

CASE 3.—The patient, a male, aged 31 years, had suffered for many years from left-sided suppurative middle-ear disease. For some days prior to being seen in consultation he had complained of marked vertigo, pain in the head, and general lassitude. Upon examination a small perforation was found in the upper and posterior part of Shrapnell's membrane. The discharge, which was scanty, was very offensive. His hearing power measured $\frac{4}{10}$ of the normal and tuning-fork tests pointed to labyrinthine involvement. The attic was carefully cleansed by means of an attic syringe, leeches were applied round the ear, and a large dose of calomel was ordered. The effect upon the patient's symptoms was practically *nil*. When seen again ten days afterwards he was lying in bed complaining very much of pain in his head and neck, of great photophobia, of sickness, and of swimming sensations whenever he moved in bed. The temperature was 97·4° F., the pulse was 56, and the respirations were 16. Marked horizontal nystagmus was present. There was no optic neuritis. The mental condition of the patient was such as to arouse the suspicion of a cerebellar abscess being present and operation was advised. The preliminary steps were as in the previous case and a free opening was made into the labyrinth through the region of the horizontal semicircular canal by the enlargement of a small fistula which was found. A disc of bone was then removed over the left cerebellar lobe and the dura mater was incised. A very free flow of cerebro-spinal fluid took place, the amount being obviously much in excess of the normal and under considerable tension. The cerebellar lobe was explored in four different directions but no pus was found. The patient made an uninterrupted recovery and is now in the enjoyment of excellent health. His hearing upon the affected side, which previously to operation had measured $\frac{4}{60}$, is now quite gone, the labyrinthine operation having destroyed the little that he formerly possessed. The case was thus one of suppurative labyrinthitis complicated with a serous meningitis.

In such cases lumbar puncture might prove to be an aid to diagnosis. Where a perfectly clear fluid escaping under tension is drawn off a serous meningitis may be assumed to exist. Where, however, the fluid escaping under tension is turbid and microscopically is found to contain micro-organisms and pus cells the existence of a purulent meningitis is certain.

PROGNOSIS.

In all cases of labyrinthine suppuration the prognosis is necessarily grave. The ever-present proximity of the pia-arachnoid membranes and the intimate relationship which exists between the subarachnoid cavity and the perilymphatic and endolymphatic spaces necessarily render the spread of septic processes from the internal ear to the base of the brain by no means improbable. The relation also of the corresponding cerebellar lobe to the posterior surface of the pars petrosa is another factor always to be remembered. Various other points must also be considered—viz., the acuteness or otherwise of the inflammatory process, its particular cause and nature, its extent and situation, and the age of the patient.

So far as the function of audition is concerned it will be found that in the great majority of cases irreparable damage is done, whilst in some cases complete destruction of the internal ear and auditory nerve takes place. In acute cases suppuration may come to an end spontaneously. Healing may then result, the affected portions of the internal ear filling up with granulation tissue which subsequently undergoes ossification.

In chronic cases the risk of extension to the base of the brain or to the adjacent cerebellar lobe must always be borne in mind and this risk is the greater the younger the patient. *According to Bezold* 20 per cent. of the subjects of labyrinthine *necrosis* die from consecutive brain and sinus affections.

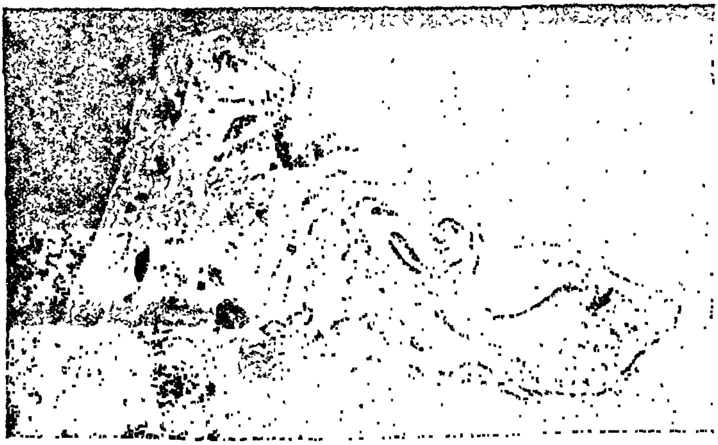
Labyrinthine [illegible] owing the exanthemata, [illegible] which are of a tuberculous [illegible] are those due to more [illegible] causes. Where disease is localised and confined to the region of the semicircular canals the prognosis is better than where the whole contents of the labyrinth are involved. In such circumstances from 20 to 30 per cent. of the cases prove fatal.

COMPLICATIONS.

Intracranial complications are frequent. From a study of recorded statistics and from observations of my own I have arrived at the conclusion that from 40 to 50 per cent. of the cases are followed by complications, usually intracranial in nature. By far the most frequent pathway of infection is *viâ the internal auditory* meatus along the sheaths of the auditory or facial nerves and the second most frequent route is *viâ* the aqueductus vestibuli.

Suppurative pia-arachnitis is the lesion most frequently met with, usually diffuse, occasionally localised. Extradural abscesses around the sigmoid sinus or over the superior semicircular canal in the middle fossa are also encountered, as are also cerebellar abscesses, developing as a rule in that portion of the lateral lobe nearest to the original focus of infection. As a factor in the production of cerebellar abscess suppurative disease of the labyrinth is of the first importance. Phlebitis of the sinus and/or of the jugular vein at times owes its origin to disease in this region. Jansen has described cases of jugular phlebitis following labyrinthine suppuration, the septic process travelling along the cochlear or vestibular veins. Of the 198 cases collected by Hinsberg the cranial cavity was infected in 108. In 43 of these cases the pathway of infection was definitely traced and was as follows. In 25 cases through the internal auditory meatus; in one case through the internal auditory meatus and [illegible] the aqueductus vestibuli; [illegible] tus cochleæ; and in eight [illegible] canals.

FIG. 4.



Temporal bone showing relation of the first whorl of the cochlea to the carotid artery and to the fenestra ovalis.

The operative exposure of the cavity of the middle ear may be the cause of the extension of latent suppuration of the labyrinth to the cranial cavity. In 169 cases of radical mastoid operation performed by Brieger for prophylactic reasons there were five deaths from meningitis and in all five the meningitis was due to a concealed labyrinthine suppuration. In one of my recent cases menin- [illegible] after the radical operation and was due to an [illegible] of the labyrinth [illegible] utcome of surgical [illegible] posterior segments [illegible] empyema of the [illegible] this situation may suddenly rupture into the meninges and produce a rapidly spreading pia-arachnitis.

TREATMENT.

In order to secure access to the external labyrinthine wall a free exposure of the middle-ear cavity must be effected. This is best secured by the performance of the typical radical mastoid operation. Sufficient bone must be removed to secure a good view of the region of the oval window. Careful search should be made under good illumination for any fistulous tract leading through the bony wall or through one or other fenestra. When found the tract should be carefully enlarged by means of the bur and the path of infection followed until all granulation tissue and purulent débris have been got rid of. This may require a prolonged and deep exploration. As the fistulous tract is in the majority of cases found in the horizontal semicircular canal the operation does not present unusual difficulties. By extending the dissection along the anterior crus of the horizontal semicircular canal the vestibule may be opened, or by extraction of the stapes and enlargement of the fenestra ovalis in a downward direction the same result may be obtained.

The cochlea may be opened up by removing the pars promontoria in a direction forwards and inwards. The first whorl is in this way rendered accessible (Fig. 4). Great care must, however, be exercised when working in this region on account of the near proximity of the internal carotid artery which occasionally runs an aberrant course and projects inwards towards the tympanic cavity. Provided, however, the field of operation is kept well illuminated and dry there *should be no fear of wounding the artery.*

In discussing the indications for operation we are faced by the fact that clinical experience has taught that in cases running a severe and acute course resolution may take place, whereas cases which appear slight and comparatively symptomless may suddenly light up and end in acute intracranial infection. I would venture to lay down the following points as guides to operation: 1. In any case of suppurative middle-ear disease where well-marked nerve deafness upon the affected side is accompanied by frequent attacks of vertigo and sickness and by nystagmus, either constant or intermittent, a careful search should be made for the presence of any fistulous tract leading into the labyrinth. If found such tract should be opened up and explored; if not found, however, an exploratory opening through the horizontal semicircular canal or foot plate of stapes is justifiable. 2. In all cases of suspected labyrinthine disease of septic origin the vestibule should be promptly opened. 3. In cases of chronic suppurative middle-ear disease accompanied by the presence of cholesteatoma and erosion of the external labyrinthine wall free opening of the area of involvement should be effected. 4. In cases of suspected cerebellar abscess accompanied by symptoms indicative of labyrinthine involvement the operative pathway should be *viâ* the middle and internal ear to the posterior surface of the pars petrosa—in other words, through the median wall of the mastoid antrum. In this way the labyrinth is opened up, the anterior portion of the corresponding cerebellar lobe is exposed, and any extradural abscess lying upon the posterior surface of the pars petrosa would at the same time be located and drained.

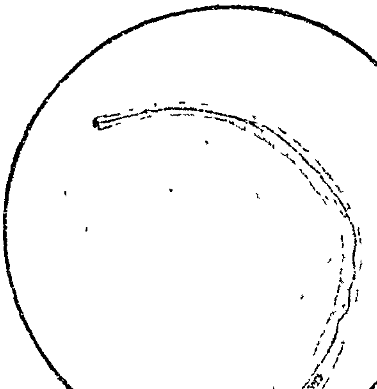
FILARIA PERSTANS AND THE SUGGESTION THAT IT BELONGS TO THE GENUS TYLENCHUS (BASTIAN).

BY GEORGE C. LOW, M.A., M.B. EDIN.,
SUPERINTENDENT, LONDON SCHOOL OF TROPICAL MEDICINE.

IN THE LANCET of Jan. 30th, p. 286, Dr. H. C. Bastian contributes a paper in which he states that it is probable that the nematode filaria perstans may really belong to some species of tylenchus and suggests the eating or other uses of bananas as the possible mode of infection. The idea of the banana having a relationship to this special filaria is based on a statement made by Christy that the distribution of filaria perstans in East Equatorial Africa corresponds almost exactly with the area of distribution of the banana cultivation and clothed people, and also *on the fact* that Bancroft has found a species of tylenchus infesting the roots of this plant in Queensland, Australia.

In a recent paper on filaria perstans[1] I pointed out that the only physical features of the land the distribution of this parasite could be found to correspond with were high temperatures and dense tropical forests, cleared zones such as the sugar cultivation areas of British Guiana or open areas such as the high grass lands of British East Africa being without it That the banana has nothing whatever to do with the occurrence or spread of this parasite is at once evident if one considers that in the West Indian islands and other areas where bananas and plantains are extensively eaten it is not found, while, on the other hand, in the virgin forests of British Guiana, in areas where there are no bananas, it exists in 50 per cent. of the aboriginal Indians. Its abundant presence in Uganda I consider to be due, not to bananas but to the fact that there is much dense tropical forest spread all over the country and that its proper intermediate host inhabits such areas. Whenever one passes out of Uganda eastwards to Kavirondo, where the land changes and grass and bushes become the predominant feature of the landscape, there the filaria disappears.

FIG. 1



Adult form of filaria perstans, head end. × 24.

Dealing next with the probability of filaria perstans belonging to the genus tylenchus, it is evident that the author of the paper has fallen into a misconception respecting the anatomy of the adult and embryonic forms of this filaria. A drawing of a species of tylenchus is reproduced and the statement is made that "this species has a blunt posterior extremity, such as is found in filaria perstans, but in others it is sharp and pointed, as in the closely allied filaria Demarquaii" A glance at this diagram shows a worm with a well marked alimentary structure, a feature which is entirely absent in the embryos of filaria perstans or Demarquaii, and, further, the anatomy depicted in the drawing in no way resembles that found in the adults of either of those two filariæ The drawing, instead of bringing out any resemblance, shows clearly that we are dealing with two entirely different nematodes In my paper already mentioned I have fully described and given measurements of the adult and the embryonic forms of the filaria perstans and it is needless to go into those in detail again here It will be sufficient to state that the adults of the filaria perstans have club shaped heads, have no spine at the cephalic end have no pharyngeal bulb and have the cuticle at the tip of the tail thickened to form two triangular appendages The embryos have the little spine which Dr Bastian mentions, have the body filled *with a column of cells, but have* no signs of an alimentary canal or any sexual differentiations The following diagrams show the difference between the adult and the embryonic forms of filaria perstans and also the difference between the embryonic forms of this parasite and filaria Demarquaii

---

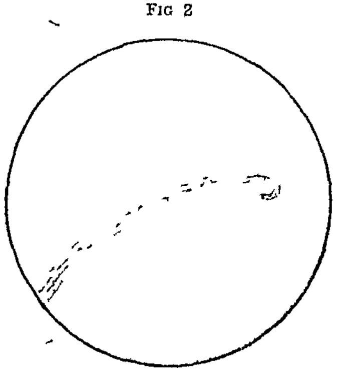
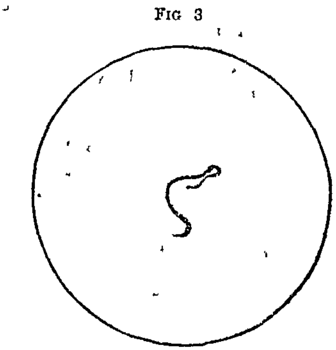
FIG 2



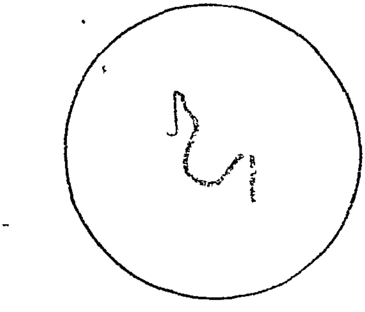
Adult form of filaria perstans tail end × 24

FIG 3



Embryonic or larval form of filaria perstans × 330

FIG 4



Embryonic or larval form of filaria Demarquaii × 330

The embryos of filaria perstans do not undergo any further change in the blood of man and the analogy of the embryonic forms of filaria nocturna and filaria immitis under*going metamorphosis* in mosquitoes shows clearly that some insect must act as an intermediate host for the further development of this parasite also From the peculiar distribution it would seem to be some mosquito or fly inhabiting forest areas

To conclude, then, filaria perstans has nothing to do with the genus tylenchus nor do bananas play any part in the distribution or spread of this filaria

IODIDE RASH IN A SYPHILITIC PATIENT RESEMBLING A VARIOLOUS ERUPTION.

BY ERNEST J HYNES, M R C S ENG, L R C P LOND, D P H,
ASSISTANT MEDICAL OFFICER OF HEALTH OF HUDDERSFIELD

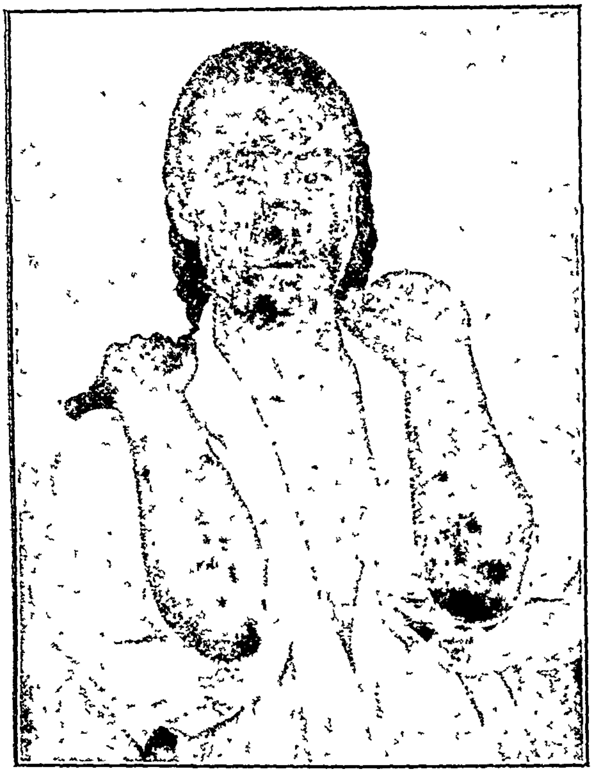
THE following case seems to be of interest from two points of view, as illustrating a difficulty in the diagnosis of small-pox and also *per se*

On May 6th, 1903, a notification was received at the Public Health Department to the effect that an in patient of a general hospital was suspected to be suffering from small-pox In short, though the history negatived that diagnosis, the appearances present were such that the medical officer of health deemed it necessary as a precautionary measure to remove the patient for isolation and observation The following history was obtained The patient, who was an unmarried woman, aged 26 years, about two years previously was laid up for a month by an illness accompanied by a severe sore throat and a rash She recovered after three months' treatment. In December, 1902, some spots appeared on the calf of the right leg, these became sores and then ulcers Similar ulcers appeared on the left leg For several days previously to the appearance of the spots there was aching of the limbs On May 4th, 1903, she went to the hospital as the ulcers were getting worse She was admitted as an in patient and fomentations were applied On the 5th her throat became sore and she was given medicine of which she took three doses On the 6th she woke in the morning and found herself covered with spots On the afternoon of the same day she was removed to an isolation ward in the sanatorium

Condition on admission —There were three good vaccination marks the total area being one and a half square inches The patient was vaccinated in infancy but not since The temperature was 100 4° F and the pulse was 100 She did not appear to be very ill She complained of pain in the tongue and throat and difficulty in speaking and swallowing Her voice was reduced to a hoarse whisper The tongue was dirty, with a deep sloughy ulcer in the mid dorsum and fairly deep serpiginous ulcers on the edges and the tip Similar ulcers were present on the tonsils, the roof of the mouth, and the soft palate. The mouth was too sore to permit examination of the larynx. There were several deep punched out looking ulcers on the calf of the right leg and others over the anterior tibial region on the left leg There was an eruption all over the body

Character of eruption —The eruption consisted of round pearly vesicles presenting exactly the appearance of those seen in small pox just before the pustular stage The vesicles were all of about equal size, the contents of many of them being blood stained There was a bulla about half an inch in diameter on the left elbow, another was on the dorsum of the right hand, and there were several over the sacrum. The contents of all these were dark and blood-stained. There were no papules

Distribution of the eruption.—The vesicles were most numerous on the face and the scalp. They were numerous on the limbs, on both flexor and extensor surfaces, more so on the forearms and legs than on the upper arms and thighs. There were a good many on the hands and feet on both palmar and dorsal surfaces. They were numerous on the back of the trunk, especially in the lumbar region and over the buttocks. There were very few on the chest and fewer on the abdomen. Unfortunately I was unable to take the photograph here reproduced (see illustration) until the third day after the appearance of the eruption, when it had lost to a considerable degree its resemblance to small pox.



Showing extent of eruption.

Previous treatment—On inquiry it was found that the patient had been given three doses of ten grains of iodide of potassium on the day previous to the eruption of the vesicles. She stated that she had taken no medicine before she went to the infirmary.

Course of the eruption.—On the second day the contents of many of the vesicles had become blood-stained and a considerable number of bullæ had appeared. They then gradually subsided, scabbed over, or burst and dried up. A few of them left small circular ulcers. The bulla on the dorsum of the hand and one over the sacrum grew to about two inches in diameter. Cellulitis developed in the adjacent tissues They were incised and extensive sloughing ensued, in the case of the hand destroying the extensor tendons and necessitating the ligature of arteries on several occasions to stop hæmorrhage When the eruption had subsided and as the syphilitic ulceration was getting worse a freely diluted mixture containing five grains of iodide of potassium with arsenic and mercury was administered three times a day. After a few doses had been taken a fresh crop of vesicles appeared and they continued to appear during the administration of the drug, which had again to be discontinued The syphilitic ulceration grew worse, the sloughing of the tissues of the back and hand continued, the tissues round some of the small ulcers left after the subsidence of the eruption began to slough, numerous petechial cutaneous hæmorrhages occurred, and the patient gradually grew weaker. On May 19th she had a hæmorrhage from the bowel, followed by another on the next day and on the 21st she died.

Necropsy.—At the post-mortem examination sloughy ulcers were found in the larynx partially destroying both vocal cords; the ulceration extended into the trachea. The epiglottis was partially destroyed by ulceration. The heart and the lungs were normal. Old pleuritic adhesions were found on the right side. The liver was small and cirrhotic. The kidneys, bladder, and uterus and its appendages were normal; the spleen was large, soft, and congested. The intestine showed patches of congestion of the mucous membrane with here and there punctiform hæmorrhages throughout its length. The condition was most marked in the upper part of the small intestine. There was no ulceration.

Diagnosis.—The patient certainly had tertiary syphilis. The diagnosis rested between (1) syphilis with small-pox (modified by vaccination); and (2) syphilis with an iodide rash. The only points in favour of small-pox were (1) the prevalence of the disease in the town; and (2) the character and distribution of the eruption. The points by which small pox was excluded were (1) the absence of any of the constant prodromal symptoms of small-pox; (2) the mature, vesicular nature of the eruption, though it had been present less than 24 hours (even on the palms and soles the spots were vesicular); and (3) the hæmorrhagic nature of the eruption unaccompanied by (at first) grave illness of the patient The diagnosis of iodide rash was confirmed by the subsequent course of the eruption, by the appearance of bullæ, and by the reappearance of crops of vesicles when iodide was re administered.

Huddersfield.

CANCER IN AUSTRALIA: A COMPARISON WITH OTHER COUNTRIES, TOGETHER WITH A SPECIFIC TREATMENT FOR THE PREVENTION AND ARREST OF THE DISEASE.

BY G. COOKE ADAMS, M.D., C M QU. UNIV., CANADA, L.R C.P., L R C.S EDIN.,

FORMERLY CHIEF OPERATING ASSISTANT TO THE LECTURER ON GYNÆCOLOGY, EDINBURGH MEDICAL SCHOOL.

THE following investigation and study into the cause and treatment of cancer were begun in 1893. Having in that year received special appointments as a gynæcologist exceptional opportunities were given me for studying this dread disease in the Commonwealth of Australia In venturing therefore to introduce to the profession what I believe to be a specific treatment in the prevention and arrest of cancer I desire at the outset to state that the theory upon which this treatment is based was arrived at only after having made a very careful study into the cause and increase of the mortality from the disease throughout the Commonwealth of Australia. Having achieved a great amount of success in arresting the pathological progress and process of the disease by preventing secondary deposits and recurrence in a large number of cases treated in connexion with my own practice I have no hesitation in stating that I believe we possess in the products of the Australian indigenous foliage—the eucalypts—all the necessary therapeutic properties for preventing and arresting malignant disease. I trust therefore that I may be able in this article to supply sufficient data, crude as they may be, to merit a fair trial of the treatment suggested.

It may be explained that in Table I. the increase of population between 1788 and 1841 was due to 70,040 male and 12,210 female, or a total of 82,250, convicts being landed in Sydney. Between 1831 and 1841 it was due to State aided immigration. In the year 1851 no less than 15,000 immigrants arrived by sea and in 1853-54-55 nearly 250,000 arrived in Victoria, which was due to the discovery of gold and the rush to that State in consequence. From 1861 to 1901 (41 years) the increase was due to the excess of births over deaths accounting for 1,910,392, and excess of immigration over emigration accounting for 780,895, or a total increase of 2,691,287. It will be noted therefore for the period between 1788 and 1851 that the large increase in population was not due to native births. It was not until 1856 that the first systematic report of deaths from cancer was recorded, at which date it showed a death rate of 14 0 per 100,000 living. It will be noted that at this period the native born death-rate was practically *nil*, owing to the fact that very few had arrived at the time of life (nearly middle age) at which cancer principally manifests itself. Therefore, as the British born proportion of the population was at this period over 50 per cent. of the total inhabitants of the Commonwealth their death-rate would show 28·0 per 100,000 living British born. In the year 1861 the Australian born proportion of the population was about 45 per cent. and the British born 46 per cent. of the total inhabitants of the Commonwealth. The Australian born death-rate at this period appears to be 5·6 per 100,000 living Australian born, while the British born was 30·5 per 100,000 living British born. In 1901 the Australian born proportion of the population had increased to 77 per cent. of the total inhabitants of the Commonwealth and the British born had diminished to 16 per cent., but it is interesting to note the fact that during this period of 40 years, while the Australian born proportion of the population had increased by about 3,000,000, their cancer death-rate had only increased to 22 6 per 100,000 living Australian born, whereas the British born proportion of the total inhabitants had only increased by about 354,000, yet their cancer death-rate had increased to 203·1 per 100,000 living British born. In other words, between the years 1861 and 1901 the Australian born death-rate had increased by only 17 per 100,000 living Australian born as against 172 per 100,000 living British born. As Table I. shows only the crude cancer death-rate it is necessary therefore before coming to any definite conclusions to study the corrected cancer death-rates for the age period 35 years and upwards of the Australian, British, and foreign born inhabitants of the Commonwealth respectively, not only in respect of the total population but also as they affect proportionately the individual nationalities themselves. These calculations I have carefully made and they are shown in the accompanying table (Table II.).

TABLE I.—*Showing the Comparative Increase in the Death-rate from Cancer per 100,000 living among the Australian born and the British born Proportion of the Population respectively and the Increase in the Cancer Death rate per 100,000 living of the Total Population from 1856 to 1901 (exclusive of the Aborigines).*

Year.	Total population of the Commonwealth of Australia.	Proportion of death-rates from cancer per 100,000 living.		
		Australian born.	British born.	Born of all nationalities
1788	1,030	—	—	—
1801	6,508	—	—	—
1811	11,525	—	—	—
1821	35,610	—	—	—
1831	79,306	—	—	—
1841	206,095	—	—	—
1851	403,889	—	*28 0	14 0
1861	1,153,973	5 6	30·5	19 0
1871	1,668,377	9 7	56·7	25·0
1881	2,252,617	16·8	72 9	32 6
1891	3,183,237	19 8	119 8	45 9
1901	3,771,715	22 6	203·1	57·3

* Calculated for the year 1856.

The death-rates are calculated for the year 1900. It will be observed that the crude cancer death-rate for the whole of the Commonwealth was 57 3 per 100,000 living, of which the Australian born cancer death-rates accounted for 17·1 and the British and foreign born 40·2, but when these death-rates were corrected for the age period 35 years and upwards the total Commonwealth death-rate was 195 3 per 100,000 living, of which the Australian born proportion was 58 2 and the British and foreign born 137·1. The relative difference between the Australian, British, and foreign born death-rates appears all the more striking when we compare them in respect to each of their proportions of living population. This I have also carefully calculated for each State separately, corrected for age period and averaged these results. Thus it will be seen that the crude cancer death-rate of the Australian born was 22·8 per 100,000 living of their population, whilst the British born is 202·1 per 100,000 living of their proportion of the population, and when these figures are corrected for ages of 35 years and upwards the difference between the two death rates is most amazing, the Australian born being only 81·3 per 100,000 living native born, whilst the British born is 490 0 per 100 000 British born. It will also be observed that for the whole Commonwealth cancer claims one death out of every 20 deaths from all causes. The Australian born proportion is one death from cancer for every 66 deaths from all causes, whereas the British born proportion is one death from cancer for every 28 deaths from all causes. When these figures are corrected for the age period of 35 years and upwards the death-rate from cancer for the whole Commonwealth is found to be one death in every ten, the Australian born one death in every 33, and the British born one death in every 14. The Australian born proportion of deaths from cancer to 100 deaths of the native born inhabitants from all causes and at all ages was 2 3, or one death in every 43, whereas the [illegible] cancer deaths to 100 deaths of the [illegible] all causes and at all ages was [illegible] e death-rates are corrected for the age period of 35 years and upwards it is found that the Australian born proportion is 6 9, or about one death in every 15, whereas the British born proportion is 12·5, or one death in every eight. The cancer death rate of the foreign born inhabitants of the Commonwealth of Australia is also very high when compared to that of the native born. The figures in Table II. show the foreign born death rate from cancer per 100,000 living foreign born to be 208·3, and corrected for the age period 35 years and upwards the death-rate is 351·6.

TABLE II.—*Showing the Crude and Corrected Death-rates from Cancer per 100,000 living, also the Proportion of Deaths from Cancer to 100 Deaths from all Causes for the Commonwealth, its Metropolitan and Country Districts; and the Comparative Death-rates among the Australian, British, and Foreign born Proportion of Inhabitants respectively for the Year 1900 (exclusive of the Aborigines).*

The Commonwealth of Australia.	Crude cancer death-rate.		Corrected cancer death-rate for ages 35 years and upwards.	
	[illegible]	[illegible]	[illegible]	Proportion [illegible] alities.
Commonwealth ...	57 3	5·0	195·3	10 0
„ metropolitan districts... ...	81 3	6 4	326 0	12 8
„ country districts	44·7	3 9	134 0	8 4
„ The native born proportion of population	17·1	1 5	58 2	3 0
„ The British and foreign born proportion of population	40 2	3 5	137·1	7·1
„ The native born proportion of population	22 8 (to 100,000 living native born).	2·3 (to 100 deaths native born).	81·3 (to 100,000 living native born).	6·9 (to 100 deaths native born).
„ The British born proportion of population	202·1 (to 100,000 living British born).	8 8 (to 100 deaths British born).	490·0 (to 100,000 living British born).	12·5 (to 100 deaths British born).
„ The foreign born proportion of population	208·3 (to 100,000 living foreign born).	8·5 (to 100 deaths foreign born).	351·6 (to 100,000 living foreign born).	11·8 (to 100 deaths foreign born).

The foreign born proportion of deaths from cancer to 100 deaths from all causes and at all ages of the foreign born inhabitants is 8·5, or about one death in 11, and these figures corrected for the age period of 35 years and upwards show 11·8, or about one death in every eight deaths from all causes. The death-rate from cancer of the foreign born inhabitants varied considerably according to their nationality, as the following list will show (Table III.). It is calculated for the year 1900. It will be noted that Italy and the United States of America show a comparatively low death-rate when compared with the other foreign countries; on the other hand, Germany, France, Austria, Norway, and Sweden show even a much higher death-rate than the British born inhabitants of the Commonwealth. The Chinese, who form the largest proportion of the foreign born inhabitants of the Commonwealth, also show a low death-rate when compared with the other foreign countries. From 1316 deaths of Chinese registered in Victoria between the years 1894 and 1900 from all causes 49 were recorded as having died from cancer. For the same period in Victoria it is interesting to learn that of 70 cases of deaths registered as having occurred amongst the aboriginals of the State only one case of cancer was recorded.

TABLE III.—*Showing the Death-rate from Cancer of the Foreign Born Inhabitants.*

From Table IV. it appears that Victoria shows a higher death-rate from cancer than any of the other States, Western Australia showing the lowest. The State of Tasmania, it will be observed, shows a high death-rate from cancer among the British born inhabitants.

A study of Table V. tells its own grim tale of the steady increase in the number of deaths and the death-rates from cancer in each State from 1870 to 1900.

TABLE V.—*Showing the Number of Deaths and the Death-rates from Cancer in each State since 1870 (exclusive of the Aborigines).*

* This table was compiled from Mr. Alfred Wolff's figures in an article on "Increase of Cancer" (*The Nineteenth Century and After*, June, 1903).

Death-rate from cancer in respect to distribution of sex.—For a number of years deaths from cancer in every State of the Commonwealth have been more numerous among males than among females. Thus, in the State of Victoria for 11 years (from 1890 to 1900) there were 8533 deaths from cancer, of which 4445 were males and 4088 were females; and in the State of New South Wales for seven years (from 1894 to 1900) of a total of 4619 deaths from cancer 2528 were males and 2091 were females. From a calculation I made of the crude cancer death-rate for the whole of the Commonwealth there was very little difference between the death-rates of males and females, but having carefully corrected the cancer death-rates for the age term of 35 years and upwards I found the average death-rates for the whole of the States to be in the proportion of six males to seven females From Tables I., II., IV., and V. it is evident (1) that the death-rate from cancer of the British and foreign proportion of the population is abnormally high when compared with that of the Australian born proportion and also when compared with Table VI, showing the death rate from cancer in their individual countries, and (2) that the death rate of the Australian born is exceptionally low, so much so that it would appear that they are almost immune from the disease when compared with the death rates of the British and foreign inhabitants and after allowing for any inherited tendency I might here mention that Mr T A. Coghlan, the chief statistician of the Government of New South Wales, has made an estimate of the children of parents dying from cancer and from the experience of seven years (from 1893 to 1899) he found that the average families of married males who died from cancer was 6 11 and of females 5 99 Of 761 persons dying from cancer in the State of New South Wales in the year 1899 of whom 281 were born in Australia 599 (285 males and 314 females) were married and of these 523 left families [1]

The question may now be asked, What then is the cause of this high death rate which has abnormally increased among the British and foreign inhabitants of the Commonwealth of Australia? A brief study of the early history of the country from 1788 to 1856 in respect to the moral and social conditions of the inhabitants, will, I venture to state throw a great light on this question It is a well known fact that Australia was the dumping ground for convicts for the first 50 years, over 82 000 having been landed between 1788 and 1841 The first population began on Jan 26th 1788 when Captain Phillip arrived in Sydney Harbour with the "first fleet' bringing with him an establishment of about 1030 people It may be as well to note the composition of those despatched from England in the six transports which made up the above establishment They had on board 564 male and 192 female convicts, 178 marines officers and men, five medical men, a few mechanics, 40 women wives of the marines, and 13 children Several shiploads followed in the same year, and in consequence of overcrowding and insanitary conditions on the voyage, it was discovered that out of a total of 1700 who had been placed on board in England, 200 died on the voyage, while hundreds of others were in an enfeebled or dying condition when they reached Port Jackson In 1803 settlement extended from New South Wales to Tasmania and later to the other States From 1800 to 1806 during Governor King s period of office, serious trouble arose from the fact that officers sent out in charge of convicts began trafficking in the rum trade and actually imported large quantities which they retailed at large profits, some of them even set up stills on their own account in defiance of Government orders This condition of affairs continued until the Imperial authorities appointed Governor Bligh to succeed Governor King believing that he would correct the abuses which his predecessor seemed powerless to suppress, particularly in regard to the rum trafficking Governor Bligh on arrival issued a stringent proclamation forbidding the bartering in spirits in exchange for other commodities but without success, as the illicit trade went on throughout his term of office It was not until he was succeeded by Governor Macquarie that this illicit traffic in spirits was rigidly suppressed and the normal and industrial condition of the colony was improved upon

From the above it is evident that *alcoholism* has played a great part as a factor in the causation of disease, from the very foundation of the country Between the years 1851 and 1861 the large increase in the population was due to the gold discoveries, and the class of individuals who arrived in Australia in consequence of these discoveries and the condition of affairs existing at this period are best told in the words of Mr Coghlan [2] "All classes and all distinctions were levelled the thirst for gold seizing upon the entire community The shops were empty, the streets deserted, the doors of the counting houses barred, the plough left resting in the furrow sheep and cattle wandered unattended while the Port of Melbourne was filled with unmanned vessels dropping to pieces for lack of attention and repair Brisk business was done by saloon proprietors and the shanty and dancing hall keepers, who became veritable 'first robbers' of fortunate diggers The public service was however, reduced to abject inefficiency, the police decamped like their superiors in search of fortune and even domestic servants male and female, joined in the general stampede The Governor was reduced to a condition of absolute powerlessness and ruled in Melbourne with hardly any to obey his behests—like a monarch without a realm Society was, in truth, utterly disorganised and it was not long before the position became even more em-

America Europe,
he port of debarka
y the myriad tents of
Van Diemen's Land,

without reckoning the other colonies, something like 11 000 people poured into Melbourne, bound for the fields in the latter half of the year 1851 The arrivals from Europe in the early days included not only what has been described by an Australian writer as the 'brain and brawn' of the whole world, but many that could have been easily spared—viz, fugitives from justice adventurers from California and the South Pacific escaped convicts and disguised bushrangers, sharpers, and professional gamblers from every city on the Continent' or in the States,' and hordes of Asiatics from Canton and the Straits Settlements, there being not less than 25 000 Chinese whom the gold fever allured to the various fields Week after week and month after month vessels sailed into Hobson s Bay, landing passengers and discharging cargoes in the most primitive fashion, for their crews deserted as soon as the ships dropped anchor or came to their moorings The nobly born and the gently nurtured, professional men and navvies, artisans farm labourers, deserting soldiers and runaway sailors 'forty niners from the fields of California, political refugees from France and Germany and Russia—representatives, in short of every civilised, and almost every uncivilised, people beneath the sun—poured in never ending stream into Port Phillip *en route* for the gold fields Upwards of 15 000 immigrants arrived by sea during the latter half of 1851, 94 000 during the year following, and in 1853-4-5 nearly a quarter of a million

To complete the above real and graphic statement of the condition of affairs existing at this period it is only necessary for me to add what Mr Coghlan may have for special reasons purposely omitted—viz, that syphilis (as well as alcoholism) was most prevalent at this period of the history of the country This dread disease in the Commonwealth of Australia has gone on its way unchecked, unnotified, and, in the majority of cases untreated for the necessary length of time to prevent the horrible ravages of this disease in later life favouring the development of malignant disease In support of this statement I may say that since 1893 from among notes on 55 cases (all females) of cancer occurring in connexion with my own practice in Melbourne I find of this number 32 or about 60 per cent, had a syphilitic history, of which 11 cases or 20 per cent, had inherited the disease and 21 cases, or 38 per cent, had acquired it from ten to 30 years previously and in nearly every instance a history of having undergone little or no treatment was elicited It may be worthy to note the region attacked by the disease in connexion with these cases The whole of the 11 cases with a history of inherited syphilis developed cancer of the breast and of the 21 cases that had acquired it 17 developed cancer of the uterus and only four developed cancer of the breast Another interesting fact was in respect to the ages of these cases The 11 cases with the inherited history were all under 40 years of age and varied from 28 to 39, whereas the ages of those with the acquired history were (with the exception of one whose age was 36 years) all over 50 years, the ages varying from 53 to 72 years Of the remaining 23 cases 17 developed cancer of the breast and six cancer of the uterus, also 12 or 21 per cent, had a history of alcoholism, eight or 14 per cent, rheumatism and three, or 5 per cent, a family history of phthisis

With regard to the history of
it may be interesting to note tha
with a syphilitic history only se
gave a history of cancer having c
one father and six mothers, whereas in the remaining 23 cases 12 or about 21 per cent gave a history of cancer having existed in their families—two fathers six mothers two sisters and two brothers The birthplaces of these 55 cases were as follows Australia 6 England 23 Ireland 12 Scotland 9 Germany 3 and France 2 It will be noted therefore that only 10 per cent were Australian born that 80 per cent were born in the United Kingdom, and that about 10 per cent. were foreign born The diagnosis in all the cases under review was confirmed by microscopical examinations As space will not permit in this article and

[2] Coghlan The Wealth and Progress of New South Wales 1900–01

as full notes on all these cases will be published at a future date, I will confine myself to the following notes on one case only which may be well worth recording, as it bears particular relation to syphilis as a factor in the cause of cancer.

A woman, aged 33 years, with her husband, was a passenger on board a steamer on which I was travelling in 1893. On the second morning after our departure the husband asked me if I would see his wife in consultation with the surgeon of the steamer who feared she was suffering from cancer of the mouth. I consented and on examination found that she was suffering from what appeared to be a syphilitic gumma of the palate, having a perforation about one-third of an inch in diameter and a thick nasal discharge. A subsequent interview with the husband left no doubt as to the specific nature of the disease. He informed me that nine years previously he had contracted syphilis and that about three months afterwards his wife was operated upon by a specialist who curetted the womb and treated her for an ulceration of the cervix, which no doubt fixed the time of the primary chancre. His wife never received any treatment beyond this and showed no further symptoms until she complained about two weeks before sailing of having a relaxed throat and a thick post-nasal discharge. Large doses of iodide of potassium were administered and the perforation had practically closed by the time we had arrived at our destination and her general condition was much improved. I continued treatment for about six months when they went to Africa. Three years later the wife consulted me for metrorrhagia. She informed me that her husband had died three months previously in Africa from cancer of the tongue and that two months before his death she had given birth to what her medical attendant described as a hydatid mole. Subsequent examination gave every evidence of this and after curetting a microscopical examination of the scrapings revealed the fact that she was suffering from deciduoma malignum or chorion epithelioma.

The chief points to be noted in this case are: (1) that both had acquired syphilis prior to developing malignant disease; (2) that the husband at the time the wife became pregnant was evidently suffering from cancer of the tongue; (3) that the molar pregnancy was either due to the syphilitic condition of both parents or to the malignant condition of the father; and (4) that this malignant tumour of pregnancy was apparently of fœtal origin. As recent research into the cause of chorion epithelioma favours that of fœtal origin, the above case may throw some light on this vexed question.

My investigations as to the prevalence of cancer among the aborigines of Australia elicited the fact that they are practically immune from the disease. Very little statistical evidence could be obtained of cases of cancer having occurred among the aborigines, although a great number had lived to the age period at which cancer chiefly manifests itself and its death rate is at its highest. On the other hand, they were particularly susceptible to bronchial and phthisical conditions, the majority dying from these causes. What, then, is the cause of this apparent immunity among the aborigines and the low death-rate from cancer among the majority of the Australian born white population? I am of opinion that the indigenous foliage—the eucalypts—exerts a great influence in this direction. The sanitary effects of this vegetation against malaria (a rare disease in Australia) are well known, as it appears to have a beneficial effect on the atmosphere in the region of its growth. The eucalyptus trees, unlike any other forest trees, have a great capacity for absorbing moisture from the soil and any stagnant water at their roots and they possess the power of giving off fresh from their leaves the water thus absorbed. The powerful disinfecting action of the volatile oils emanating from their leaves and other parts is mainly due to the fact that they change the oxygen of the atmosphere into ozone and peroxide of hydrogen. The foliage dropped on the ground does not decompose like that of most forest trees but purifies any germ-infected matter in pools of stagnant water on the ground. The indigenous soil of Australia which grows the food for the cattle possesses sanitary properties which may have an indirect action on the health of the same. Although I have made investigations and examined many indigenous animals such as the opossum and kangaroo for malignant growths, I have never been able to obtain any evidence of cancerous disease among them; whether living on the gum leaves is the cause of this immunity would be interesting to know. I am inclined to believe such to be the case. On the other hand, malignant growths are prevalent among the cattle but not nearly so prevalent as among the cattle of other countries, as statistical evidence proves.

Mr. Wolff's investigations into the cause of the increase of cancer in various countries appear to prove conclusively that regions of high cancer mortality are also for the most part regions of woods and forests. He states: "The facts on this point were everywhere so striking that they seem to establish beyond question that a focus of cancer infection is to be found in regions abounding in woods and water." Lloyd Jones, writing in 1899 on the different conditions in Cambridge under which cancer was observed, says: "Proximity to trees, especially large ones, is connected in some way with the prevalence of cancer. The part of the town which is most free from cancer is singularly devoid of trees and vegetation, while the disease is very prevalent in well-wooded parts of the town and among houses hemmed in by trees." Other observers have noted similar facts. Therefore, should Mr. Wolff's conclusions be correct they only add additional weight to my theory that the Australian eucalypts and their soil possess some specific action in preventing malignant disease among the aborigines and the majority of the white Australian born proportion of the population of the Commonwealth. It is interesting to note that these countries, such as Italy, the United States, Portugal, and Algeria, which have transplanted or possess the eucalyptus foliage, show a low death-rate from cancer. India, which possesses the cajuput tree—belonging to the same natural order as the eucalypts and producing a volatile oil having medicinal properties somewhat similar—also shows a low death-rate from cancer among the native born population In fact, the native born population of all countries possessing trees and foliage belonging to the same natural order (myrtaceæ) as the eucalypts or their allied species (lauraceæ) appear to have a great immunity from cancer, the sanitary properties of the various species no doubt exerting an influence in this direction. Compare this with that of the wooded forest regions referred to by Mr. Wolff, the dropping foliage of which decomposes, becomes germ-infested, influences the stagnation of the water, and renders the soil insanitary, thereby becoming a great factor in the cause of the high death-rate from cancer in these regions

Another important fact which appears to support this view and at the same time throws much light on the cause of cancer is that the native population of countries possessing this foliage, although subject to all varieties of neoplasm, very rarely have malignant new growths. Scirrhus of the breast and rodent epithelioma of the face are instances in point, the scarcity of the former being no doubt due to the fact that the corset, which to my mind is the principal exciting factor in the cause of cancer of the breast, is an unknown quantity, and of the latter probably being due to the fact that the pigmented skin of the native is better protected from irritation by the rays of the sun. My investigations have proved that most cases of cancer occurring among the native populations where the various sanitary foliage referred to is indigenous to the country, such as Australia, India, Batavia, Singapore, Ceylon, China (Formosa), Japan, Zanzibar, Penang, Bencoolen, Amboyna, and other places, are undoubtedly due to some prolonged local irritation acting on a debilitated constitution. Take India for instance, kangri cancer is very prevalent among the kangri wearers, due to the constant irritation of the kangri on the skin of the abdomen; Dr. W. J. Elmslie, Dr. J. N. Mitra, and Dr. Neve have conclusively proved this to be the case. Dr. Neve has quoted over 400 cases and has shown that the disease is no doubt an epithelial cancer, accompanied by glandular infection, ending in death unless cured by operative means. Then, again, it has been clearly pointed out by many observers that epithelioma of the penis is very prevalent among that portion of the native population —the Hindoos—who have long foreskins and do not circumcise. On the other hand, it is almost absent among the Mussulman portion of the population who are all circumcised The Jews for the same reason appear almost immune from this form of the disease, while on the other hand phimosis appears to be a great factor in the causation of cancer of the penis in most European countries.

Cancer of the lip appears to be very rare among natives of India, owing no doubt to the absence of smoking the short clay pipe; whilst, again, cancer of the mouth is very common, which is no doubt due to the constant habit of chewing irritating substances such as tobacco, betel leaf, &c. Now when we consider these facts and also the amount of malignant disease in European countries due to similar causes—such as the prolonged irritation of the pipe on the lip, phimosis on the penis, soot on chimney-sweeps' skin, chewing tobacco on the mouth, corset on the breast, stiff collars and shirt on the skin, and constant use of pessaries on the uterine organs—I venture to say that there is sufficient evidence to warrant one in believing that next to hereditary causes prolonged local irritation is the principal exciting factor in the cause of malignant disease. But from the number of individuals who live up to, and long past, the cancer age, and who are subject to prolonged local irritation on all their tissues from more or less all of the above causes and who never develop malignant disease, it would appear that some other factor is wanting in addition to prolonged local irritation. I venture to state that I have found no evidence in my investigations to warrant me in believing that this factor will be found in the laboratory by those searchers after the bacterial and parasitic cause, but I have found ample evidence in favour of my theory that this factor is to be looked for by the chemist in the form of a chemical constituent in the blood, occurring chiefly in the debilitated constitutions of those arriving at the cancer age, due to such neglected and untreated diseases as syphilis, alcoholism, obesity, rheumatism, gout, tubercle, &c. There is every evidence also to believe that sugar and alcohol play a great part among the exciting causes inasmuch as they enter very largely into the manufacture of beer, sweet wines, and spirits. This fact probably accounts to a large extent for the great contrast in the death-rate from cancer in Australia between the metropolitan and country districts as seen in Table II., the larger amount of beer which is consumed in the metropolitan districts favouring a higher death-rate than in the country districts where less beer is consumed. The same reason may partly account for the very high death-rate among the British and foreign born proportion of the Commonwealth, compared with the Australian born, as the former consume considerably more beer than the latter, who drink more wines and spirits. This fact was particularly striking in France where, according to Mr. Wolff, the contrast was very marked between the departments of high cancer mortality, in all of which beer is very largely drunk, and the departments in the centre and the south, where the death-rate from cancer among the wine-drinking population was persistently low, his conclusion being "that the consumption of beer has a distinct influence on the development of cancer."

Hereditary causes.—My investigations lead me to believe that the hereditary causes of malignant disease may be subdivided into two groups—viz., "inherited" and "congenital," the former being those that in the strict sense are inherited as the result of direct action of the malignant virus upon the sperm cells and germ cells prior to, or at the time of, impregnation, either parent at the time suffering with a malignant diathesis, such cases no doubt being those which develop late in life, the pathological development being accelerated by some one or other of the exciting or irritating causes. Numerous cases are on record of members of the same family having developed malignant disease. I might here mention that in one of my cases—that of a woman who developed cancer of the uterus at 60 years of age—there was a history of two brothers [illegible]

The latter or congenital group are those that are acquired by the fœtus during its intra-uterine life, in which case the medium of infection would be the placental circulation; this group of cases develop either in utero or in early life. As instancing this class of case there was reported in the State of New South Wales in the year 1898 one death from cancer, the patient being two years of age. In 1899 there were deaths registered of two children aged two months, and of three aged three years, and there were altogether six deaths of children under five years of age. The fact that the whole of these cases were certified to by qualified and experienced medical practitioners proves beyond doubt that they were congenital, unless grave errors of diagnosis were made by the medical practitioners concerned. Many such other cases are on record.

Is malignant disease infectious or contagious?—The fact that numerous observers in many countries have of late years collected a large amount of evidence showing its frequent occurrence in certain streets and houses which latter have been termed "cancer houses," also the numerous instances which have been recorded of the disease having been transmitted from husband to wife and *vice versâ*, and to different individuals who have been drinking from the same vessel or have smoked the same pipe which had been constantly used previously by one suffering from cancer, leave very little doubt that some forms of malignant disease are contagious. I have no hesitation in my own mind in stating that the majority of the infectious or contagious types of cancer will be found on careful investigation to be a form of malignant syphilis.

The theory that I venture to advance as the result of this investigation and upon which the following specific treatment was based is briefly as follows. That the origin of cancer (carcinoma and sarcoma) is not due to a bacterial, parasitic, or local cause, but is to be looked for in the blood in the form of an unknown chemical constituent (which, for the purpose of description, I will call "malignic acid"), capable of gradually becoming virulent under certain bad climatic, hygienic, dietetic, and social conditions of life, chiefly manifesting itself at its greatest virulence after 40 years of age, the degree of virulence and the age at which it may manifest itself being entirely dependent upon the age and constitutional condition of parents at the time the "malignic acid" diathesis is transmitted and according to the mode of living, environment, and exposure to the exciting causes after birth. This "malignic acid" when excited into virulence in its passage through the blood stream may attack any soft or bony tissue in any part of the body the physiological resistance of which has been weakened by one or other of the exciting causes. It matters not whether this tissue be epithelial or connective, a matrix of detached embryonic inclusions; existing benign tumours derived from a congenital, inherited, or post-natal origin; syphilitic, scrofulous, tuberculous, or lupoid lesions; ulcerations and lacerations of the cervix uteri; inflammatory deposits, old scars, burns, wounds, or skin lesions excited by soot or [illegible] or any other irritating cause. Th[illegible]sses the power by a process of [illegible]nsforming any of the aforesaid weakened tissue into malignant tissue, having particular effect upon debilitated epithelial and connective tissue which has been subjected to prolonged local irritation, attacking and infecting its intracellular matrix and cells. At the same time, it sets free the latter to group together in nests or to migrate through the blood and lymph channels either to escape as excretory products or to become deposited on other distant debilitated parts of the body. I am of opinion that the various so called intracellular and cellular inclusions which have been isolated and so fully described by Plimmer, Schueller, von Leyden, and others to be parasites and by Nosske and Greenhough as secretion deposits are nothing more or less than the transformed remains or deposits (which also for the purpose of description I will term "malignates") of the parent intracellular matrix, some of which has been included in the cells during the process of chemical reaction.

The many varieties of malignant growths and lesions, cellular and otherwise, which already have been determined by pathologists, favour, I venture to say, the above theory. Malignant lesion or growth, it is now well known, does not depend upon the amount of cellular elements found therein, as this to a great extent depends upon the structure of the tissue involved. The numerous cases of malignant disease which the microscope has failed to determine prior to operation or ante mortem and which have subsequently been [illegible] such after removal or post-mortem examination [illegible] theory." The severe con- [illegible] form of emaciation and cachexia, frequently accompanying malignant disease, and which are out of all proportion to the severity of the local or primary lesion, also support this view.

The following case which came under my notice in 1893 clearly demonstrated to me that any successful treatment for the arrest of cancer should not depend alone upon attacking or removing the accessible primary lesion. I had occasion to perform a post-mortem examination for a coroner's inquest upon an old man, 72 years of age, who had committed suicide by cutting his throat and hacking the same in a most deliberate manner, and although the cause of death from suicide and hæmorrhage was apparent, the law demanded a complete necropsy. Upon performing this the real motive for the poor old man's suicide was made evident. Masses of cancer nodules were found to be studded over the liver, the kidneys, under the pleura, the pericardium, and the endocardium, and although I made a careful search both externally and internally for some primary lesion of considerable size to account for such extension I could not discover one.

In the report in THE LANCET[3] of a meeting of the Pathological Section of the Royal Academy of Medicine in Ireland Dr. J. T. Wigham showed a cancer of the breast and various internal organs secondarily affected, with sections. The cancer was of the scirrhus type, the interest of the case lying in the route by which the disease is said to have spread to the internal organs. Cancer nodules could be discovered in the liver and under the pleura, the pericardium, and the endocardium, and the sections showed the growth pushing through the heart fibres between the last two. Similar growths were also found in both ovaries and along the course of the Fallopian tubes. Many other similar cases have been recorded. From the above facts it is plainly evident that treatment of a so-called accessible primary lesion (which oftentimes may be only a secondary growth) *alone* after the malignant virus has become active is tantamount to treating a syphilitic chancre, gouty, rheumatic, or tuberculous deposit locally, while permitting the secondary lesions to form. I hold, therefore, that as the origin of cancer is in the blood numbers of so-called primary lesions or growths may manifest themselves simultaneously in different parts of the body, which may be internal or external, inaccessible or accessible. That from the moment the malignant virus becomes active, proliferation and degeneration of the tissue and cells in the region attacked commence, and secondary infection and deposits occur. That the only method of arresting these pathological conditions is to charge the blood with some antidote to the malignant virus which it contains capable of rendering both the virus and the infected migrating cells in the blood and lymph channels inert, at the same time removing or attacking directly the primary lesions when accessible at the earliest possible moment.

(*To be continued.*)

AN UNUSUAL CASE OF CEREBRAL ABSCESS; BILATERAL TEMPORO-SPHENOIDAL ABSCESS; OPERATIONS; RECOVERY.

BY A. L. WHITEHEAD, M.B., B.S. LOND.,
OPHTHALMIC AND AURAL SURGEON TO THE GENERAL INFIRMARY, LEEDS.

SUCCESSFUL operations upon abscess in the temporo-sphenoidal lobes of the cerebrum secondary to disease in the temporal bone are now comparatively frequent, so that isolated cases are rarely published. Many cases also are known in which operations have been performed upon two or more abscesses on the same side of the cerebrum, but after a careful search no record has been found of a case in which the temporal lobes on both sides have been destroyed by abscess secondary to ear disease. Such a condition must necessarily be very rare and recovery after operation, if not unique, is sufficiently remarkable to justify publication.

On May 9th, 1901, I was asked by Dr. C. Oldfield of Leeds to see a young woman, aged 20 years, who was then comatose and had a purulent discharge from both ears. The history, as supplied by her friends and the medical attendant, was that she had suffered from an intermittent discharge from both ears for six years but was otherwise very healthy. About the middle of March she had had severe pain in the left ear which lasted a few days, and subsequently, although not feeling very ill, she had not been able to resume her usual work. For three weeks there had been constipation and almost constant headache on the left side and during the same period she frequently complained of dizziness. Three days before I saw her she complained of diplopia but no distinct strabismus could be detected. For two days periods of mental dulness had been noticed and there had been marked drowsiness, gradually passing into complete unconsciousness on the last day. Vomiting had only occurred twice, once seven days and once two days before coming under my care, each time after food. No paralysis of any of the limbs had been noticed before May 9th and no pain, swelling, or tenderness over the mastoid region. The temperature had been normal or slightly subnormal.

The patient was removed to the General Infirmary for operation. On admission she was found to be profoundly unconscious and could not be roused. The limbs were motionless but there were some rigidity of the right arm and occasional involuntary contractions of the pectoral muscles on the same side. The knee-jerks were present and brisk. Both eyes deviated outwards, the right deviating more than the left. The pupils were equal and reacted slightly to light. They were for the most part very small but at fairly regular intervals of from 20 to 30 seconds they suddenly dilated almost to the fullest extent possible. Synchronous with this the breathing for four or five respirations was deeper and there were slight movements of the arms and legs; the breathing then suddenly became feeble and the pupils contracted at once. There were no gradual rise and fall in the amplitude of the respirations, as in the usual form of Cheyne-Stokes breathing. The respiration-rate was from 18 to 22 per minute, the pulse was 56 and somewhat irregular, and the temperature was 98·2° F. The outer margins of the optic discs were blurred, the inner margins being distinct. Examination of the ears revealed pus in both auditory canals. On the right side there was a perforation in the membrana tympani involving the lower third; on the left a polypus filled up a perforation in the anterior half of the drum. Within an hour of her admission she was anæsthetised and the left mastoid region having been exposed by the usual curved incision the outer surface of bone was removed and the antrum and mastoid cells were found to be full of pus, caseating material, and granulation tissue. The usual radical mastoid operation was performed, all diseased bone being removed. In the performance of this the dura mater over the tegmen antri was exposed but appeared smooth and healthy. A portion of the squamous portion of the temporal bone immediately above the tegmen antri was removed with a trephine; the surface of the dura mater was healthy but the brain did not pulsate. The dura mater was opened by a curved incision and the brain was explored with a glass tube three-eighths of an inch in diameter. An abscess was found about one inch from the surface and more than three and a half ounces of stinking greenish pus and broken-down brain matter were evacuated. Two drainage-tubes were inserted and the amount of semi-solid material in the abscess being large the cavity was syringed out with boric acid lotion. One tube was left in and the mastoid wound was packed with iodoform gauze. On the following day the pulse was 82, the respirations were 20 and quite regular, and the temperature was 98·8°. The pupils were equal, reacting to light and not exhibiting the periodic variations noted above. The rigidity of the right arm persisted and she remained unconscious but resented interference.

On the second day some return of consciousness was noticed and the rigidity of the right arm passed off. The excreta were still passed involuntarily. In the afternoon there was a short rigor during which the temperature rose to 104·8°, afterwards falling to normal, from which it did not again rise during the convalescence.

On the fourth day after the operation she recognised her friends and regained control over the urine and fæces. As discharge persisted from the abscess cavity for some time the tube could not be removed until 26 days after the operation. As soon as consciousness was recovered a marked amnesic aphasia was noticed which only slowly passed away. Three weeks after the operation she wrote the names of her brothers as "Tom" and "Alfrom," knowing, however, that the latter was incorrect. Her perception of colours was accurate and her sense of taste and smell was quite unimpaired. Ammonia could not be named until she had taxed her memory for nearly three minutes, although she at once remembered that it was used for washing purposes and was to be obtained at a druggist's shop. A certain amount of mental instability was present; she was very easily excited and would laugh immoderately on the least provocation and was also easily moved to tears.

The patient left the hospital 37 days after the operation, the wound being healed and her mental condition being almost normal. 18 months later she was apparently perfectly well and got married. She was advised to have a radical operation upon the right mastoid, discharge from that ear still persisting, but her hearing power for conversation being almost perfect she could not be persuaded to consent to this

---

[3] THE LANCET, Dec. 26th, 1903, p. 1784.

On Nov 11th, 1903, I was again asked by Dr Oldfield to see the same individual She had been in excellent health, with the exception of a persistent painless otorrhœa on the right side, up to eight weeks previously, when she commenced to suffer from headache chiefly on the right side For three weeks she had felt ill, the appetite being poor and the bowels constipated For a fortnight there had been occasional vomiting, some days not at all, on others two or three times in the 24 hours During the preceding three nights there had been slight delirium and during the days an increasing drowsiness, the temperature being constantly subnormal and the pulse about 80 When seen on the 11th she was very drowsy but resented interference and complained constantly of intense pain on the right side of the head The temperature was 97°, the pulse was 72 and the respirations were 24 The pupils were equal, they reacted to light, and were of average size There was no optic neuritis The knee jerks were present and there was no rigidity or paralysis of any limb There was no tenderness or swelling over the mastoid The right auditory canal was full of pus, the drum was absent, and the bottom of the canal was filled with granulation tissue The diagnosis was complicated by pregnancy of three months' duration, but it seemed clearly to point to intracranial suppuration secondary to the ear disease on the right side

The patient was removed to the General Infirmary for immediate operation The right mastoid was opened in the usual way and was found to be completely excavated and filled with stinking pus and broken down cholesteatomatous material A radical mastoid operation was performed The bone forming the roof of the antrum and middle ear had been entirely destroyed by the disease and the dura mater, covered with granulation tissue, was exposed Pus could be seen exuding through a small opening in the dura mater The ridge of bone between the tegmen antri and the squamous bone was removed, together with a portion of the latter bone itself The dura mater over the inferior temporo sphenoidal lobe being thus well exposed was opened, the incision being carried downwards to the point where pus was exuding The underlying brain was incised and more than three ounces of very offensive pus gushed out The abscess cavity was cautiously explored with the little finger and was found to extend upwards for more than two inches and forwards and backwards for about one and a half inches in each direction The lining membrane feeling very delicate the cavity was not washed out but a large drainage tube was inserted The pus was found to contain a pure culture of the bacillus coli communis

On the following day there was a slight discharge from the tube, the temperature was 100°, the pulse was 92, and the patient's mental condition was much improved On the fifth day the discharge was very slight the pulse and temperature were normal, her mind was quite clear, her appetite was good, but constipation was still marked The tube was removed on the sixteenth day She left the hospital a month later, the wound being healed and her mental condition being perfectly natural

On both occasions the points by which the diagnosis was established were the presence of a chronic otorrhœa, severe unilateral headache, subnormal temperature, slow pulse drowsiness progressing into coma, and occasional vomiting These are the only signs usually present in uncomplicated cases of temporo-sphenoidal abscess From the size of the abscess the second and third temporal lobes on both sides must have been practically destroyed On the first occasion the rigidity of the right arm and the aphasia indicated pressure upon, or extension of inflammatory œdema to, the [illegible]

. . . . .

In the case now recorded taste and smell have been very carefully tested with a variety of objects, each side and the tip of the tongue and each nostril being separately examined, but no defect whatever can be elicited The hearing power on the left side, upon which the first operation was performed, is the same as after that operation and is reduced to ability to hear a loud whisper at a distance of six inches The deafness is fully accounted for by the extent of the ear disease present before the operation was performed On the right side a low whisper is heard at a distance of 30 inches, a watch at ten inches which a normal ear hears at 40 inches, and the ordinary speaking voice can be clearly heard at five feet Although the disease must have destroyed the lower temporal lobes of the cerebrum on both sides taste and smell are absolutely perfect and the hearing power is so little affected that ordinary conversation can be followed with the greatest ease The memory and general mental power are also absolutely unimpaired

Leeds

ON LATENT OR INTERMITTENT NASAL OBSTRUCTION.[1]

BY MAYO COLLIER, M B, M S LOND, F R C S ENG,
SENIOR SURGEON TO THE NORTH WEST LONDON HOSPITAL AND EX PRESIDENT OF THE BRITISH LARYNGOLOGICAL ASSOCIATION, ETC

THE object of my communication to day is to ask you to consider with me a condition of things within the nose that up to the present has scarcely been entertained by rhinologists and certainly not with the apprehension that this condition was one of any moment or worthy of much consideration I want to point out to you that there is a condition of things within the nose which is extremely common, that this condition, although extremely common, has escaped general recognition, and that this condition of things is potent for harm and is a source of many of the affections found within the throat, ear, nose, and post-nasal space The terms "latent" or "intermittent" nasal obstruction are sufficiently descriptive of the condition I wish to discuss with you this afternoon I suggest to you that apart from the various forms of nasal obstruction due to growths, out growths, deflections, or what not, with which we are all familiar, there is a form of nasal obstruction that is more common and more harmful than all these put together This form of nasal obstruction is latent—that is to say, it may come on in a nose that is physiologically perfectly patent and in which there is nothing abnormal to be seen This form of obstruction may alternate with a condition of things in which the functions of the nose are perfectly performed and yet for 12 hours out of the 24 the nose may be absolutely occluded and the patient in a condition of extreme misery and discomfort This intermittent form of nasal obstruction often eludes recognition and the surgeon is led astray because at the time of his examination the nasal chambers are perfectly free and patent and the functions of the nose are perfectly performed I feel sure that no one present would resent the suggestion that more or less complete obstruction of the nasal chambers might be harmful to the individual and might lead to ear, throat or nose troubles If you admit that constant nasal obstruction is in many cases a cause of ear, throat and nose troubles, I am not straining your imagination when I ask you to believe that intermittent nasal obstruction is also powerful for harm in the same direction Or in other words, if continuous loss of the functions of the [illegible] throat, and ear I am here [illegible] of the functions of the nose has a similar effect

This then, is the subject matter of my remarks to you to day In order to understand properly this question we must have a clear idea of what are the functions of the nose and how the physiology of this organ is related to the physiology of the surrounding organs and to the economy in general The nose has important relations with respiration, with digestion with audition, with speaking and singing, with taste and smell, with sight, and with the various emotional states The nose may also be looked upon as a respiratory organ in itself, as it is certain that a considerable interchange of gases takes place in its recesses and cavities There is also some reason to believe that the nose is the safety valve of the brain In order to appreciate fully the effect of the loss of the functions of the nose and the harm that may in consequence accrue to the individual we must first be in a position to appreciate their value This can only be done by a careful survey and accurate knowledge of these functions as far as we are able In order to obtain this we will discuss *seriatim* the nose in relation to the various functions I have enumerated

---

[1] A communication read before the British Laryngological, Rhinological, and Otological Association on Jan 29th, 1904

And first of all with respiration and so through respiration with the circulation and oxidation of the blood. As baldly stated in the physiology books the nose warms, moistens, and filters the air, but how this is accomplished the learned writers of text-books have not attempted to explain. At first it is a little difficult to see how a stream of air some 30 or 40 cubic inches in value can become warmed, moistened, and filtered whilst passing through the nose in the space of two seconds. When, however, we examine the upper respiratory tract as a whole we see that it is not a channel or tube of one uniform calibre but that it presents several remarkable constrictions that alternate with equally remarkable expansions. We then begin to see that these constrictions prevent the very thing from taking place that we are told does take place—viz., that the air from the exterior passes slick through the nose from front to back and on into the lungs in a solid more or less cylindrical stream and does not mix with its surroundings. This is manifestly incorrect. If we look at the upper respiratory tract and view it as a whole we shall be surprised at the variations that it presents. Commencing with the external nares we find that the vestibule becomes narrower as it passes inwards and joins the nasal chamber opposite the nasal process of the superior maxillary bone. The vestibule or inlet to the respiratory function is cone-shaped and at its junction with the nasal chamber becomes so contracted as to constitute perhaps the narrowest point in the whole respiratory tract. It is curious to note that whereas the external nares are capable of expansion and contraction the calibre of the upper respiratory tract at its junction with the nasal chamber is rigid and unalterable, being surrounded by bony and cartilaginous borders. A limit is thus put to nasal respiration by the size of the anterior opening of the nasal chamber. After passing this narrow spot in the respiratory tract we find that the canal expands in a remarkable manner into the nasal chamber, which with its recesses constitutes a cavity of considerable dimensions. These recesses must not be dismissed from our calculations when studying the act of respiration. It is as sure and certain as anything can be that these recesses act *not only* as resonance chambers to the voice but as warming and mixing chambers, so that the air as it is admitted from the exterior in a raw and unprepared state is mixed with the contents of the nose and its recesses and so made ready to pass on into the pharynx and upper tubes.

An observation I had the advantage of making on a healthy frontal sinus will go a long way in substantiating this fact. I opened a frontal sinus for exploratory purposes, and being very careful I removed the button of bone without injury to the lining of the sinus. At each inspiration the lining membrane was depressed and at each expiration bulged into the wound, proving incontestably that part of the contents of the nasal sinus is withdrawn during inspiration, to be replaced during expiration. The air then entering by the cone-shaped vestibule must do so with an increasing rate of speed till it has passed the narrows of the anterior opening. It must here lose much of its velocity and becoming slowed down will distribute itself in all directions, as regulated by the shape of the delivery tube of the vestibule. It is thus seen that as a stream of air it must be subject to and conform to the shape of the tract through which it passes and that the rate of motion of the air will be an average between the rates of motion in the narrowest and widest parts of the respiratory tract.

Passing onwards we come to a second marked narrowing, that of the posterior nares. This is crescent shaped and varies with the size of the posterior end of the inferior turbinal body. The cross section of this opening can only be a very small fraction of the cross section of the nasal chamber. Consequently the air in its passage backwards must be greatly delayed by having to pass this constriction, thus allowing time for the necessary warming, moistening, and filtering of the inflow. Following on this constriction is a remarkable dilatation, that of the pharynx extending from the base of the skull to the upper opening of the larynx. The nasal contents having passed the posterior opening of the nares linger in the pharynx and pass slowly on but with increasing speed to the larynx. The act of warming, moistening, and filtering is continued in the pharynx. So far we have traced the inflowing air to the larynx, and can surmise that the anterior and posterior constrictions of the nasal chamber serve a very good purpose in delaying and slowing down the air in its passage through the nose. The narrow anterior opening or inlet insures that the inflowing air shall be distributed and mixed with the nasal contents. The posterior constriction prevents the too rapid emptying of the nasal chambers by the powerful aspiration of the lungs. It is curious to note the alteration in the positions of the contents of the respiratory tract from the commencement of inspiration. At the commencement of inspiration the air in the bronchial tubes will pass in and fill the bronchioles and vesicles. The air in the larynx and trachea will follow on into the bronchial tubes and the air in the pharynx will pass on and take the place of the air in the trachea and large tubes, whilst the air in the nasal chambers will flow into the pharynx, larynx, and trachea. We thus see that the air passes in and mixes with and dilutes the impure reserve and residual air but cannot displace it. During respiration the impure expirate extrudes the contents of the pharynx and nose and fills the upper respiratory tract. This, no doubt, undergoes considerable purification in the chamber and recesses of the nose in the interval before the next inspiration.

I would here remind you whilst on the subject of respiration that this is the supreme function of the economy. The circulation and oxidation of the blood, not only in the systemic but portal system, is dependent on respiration. It is not unreasonable to suggest to you that any interference with the function of respiration and so with the proper oxidation and circulation of the blood for a considerable period in the 24 hours must be harmful and baneful to the individual. The functions of the nose are closely related to the functions of digestion, both directly and indirectly—directly by the interference with mastication that follows an obstructed nose. A person with his nose occluded cannot shut his mouth sufficiently long to masticate his food properly and consequently bolts the same before it is half divided to the detriment of his stomach. Again, the congestion of the pharynx and post-nasal space incidental to, and associated with, nasal obstruction upsets the stomach in more ways than one—directly by the amount of unhealthy mucus that passes into the stomach and indirectly by the constant irritation of the pneumogastric centre by the branches of the pharyngeal plexus.

The insanitary state of the mouth that follows mouth-breathing and the amount of contaminated and dusty mucus that must pass into the stomach (or what has been properly termed oral sepsis) is a considerable disadvantage to digestion. Seeing that the whole of the circulation of the liver and abdominal organs is carried on by the respiratory act, any interference with this must be of serious detriment to the absorptive functions of the alimentary canal and so a fertile source of slow digestion and other forms of dyspepsia. Digestion and respiration are so intimately associated that I seldom meet with a patient suffering from nasal obstruction in a marked and chronic form who escapes from symptoms of indigestion, sluggish liver, or other abdominal troubles.

Now what relation have the functions of the nose to the eye? The nose is the drain of the conjunctival sac. Nasal obstruction will cause epiphora and conjunctivitis and other troubles. The two functions are intimately and sympathetically associated. The same nerve and the same artery supply both. Any irritation in the nose is responded to by flushing of the conjunctiva and watering of the eye. The nose is the guardian of the eye. A strong light detrimental to the retina will cause sneezing and so prevent further damage by altering the position of the head and casting the

Horizontal cross section through cochlea, tympanum, and external ear of rat about fourth week.

eyes to the ground or closing them altogether. Congestion in the nose will be followed by fulness of the retinal veins and congestion of the conjunctiva. The nutrition of the nose and eye are intimately associated. The ophthalmic and sphenopalatine ganglia are anatomically and physiologically closely related.

Passing on to the relations of the nose to the ear it is not surprising to find that these are peculiarly sensitive. The middle ear or tubo tympanum is developed from the nose by two finger like prolongations. It is simply a prolongation of the nose cavity. The cavities of the nose and ear are practically one. Any increase or decrease of tension within the nose is immediately felt and communicated to the contents of the ear. It is not difficult to realise that whatever affects the main cavity of the nose will affect its various recesses and prolongations. The unity of the nose and middle ear must be taken into consideration and fully realised as the first and essential step in the proper understanding and treatment of many of the affections of this cul de sac. There is little doubt that in normal nasal respiration both inspiration and expiration are felt in the tympanic cavity and that a slight movement of the membrana tympani takes place inwards with inspiration and outwards with expiration, the same as has been recorded in the frontal sinus. In corroboration of this may be mentioned the fact that when one is listening very carefully for a sound the mouth is opened and respiration is suspended or carried on very gently by way of the mouth in order to annul (I suggest) the oscillations incidental to respiration.

The relations between the functions of the nose and the voice are peculiarly apparent. Besides preserving the covering of this organ in a healthy condition the nasal chamber is the delivery tube of the voice as well as its resonator. The functions of smell and taste are almost entirely dependent on the patency and proper functioning of the nose and must be entirely annulled if the nose be occluded. And lastly, there are some grounds for supposing that the nose is the safety valve of the brain by acting as a drain to the arachnoid cavity. We know that the arachnoid sheath is continued through each opening in the cribriform plate and surrounds the olfactory nerves almost to their terminations. The confusion of intellect, the forgetfulness the difficulty of concentrating the thoughts, the headache, the morning drowsiness, and other mental symptoms that are associated with nasal obstruction may well be due to increase of arachnoid fluid and congestion following on nasal obstruction and the consequent arrest of the functions of the nose. There may be some reason also, for believing that some at least of the large quantity of moisture that is taken up by the inspired air comes from the arachnoid fluid. Again the pathological conditions known as hydrorrhœa where pints of fluid are discharged from the nasal cavities, associated with polypi and other abnormal states, can more easily be explained by the assumption of an outflow from the arachnoid extensions into the nose modified possibly by infiltration. In order to remind you of the relation of the functions of the nose to the emotions I would ask you to imagine Mr Tree or Sir Henry Irving in any of their great parts with an obstructed nose and an open mouth. The emotional display of the face would be quite impossible and these actors' efforts ruined.

The relations of the nose to the sexual function is well marked in some of the carnivora but may, I think, be altogether discarded when dealing with the genus homo.

Now you will agree with me that the nose is not an unimportant or idle organ and is well worthy of your best care and consideration. I will now return to our main subject and explain to you more fully what is meant by latent or intermittent nasal obstruction, the mechanism of its production, its diagnosis, and lastly, if I have time, I shall say a few words as to treatment. I can more easily explain to you the exact condition to be known as latent or intermittent nasal obstruction by citing you one or more out of the large number of cases I have records of. In 1895 I was consulted by a medical man who gave the following account of himself. He was 63 years of age and for the last 14 or 15 years he had been troubled with his nose becoming occluded at night and at other times. His general health he said was indifferent he was easily fatigued, and suffered from flatulent dyspepsia headache and deafness. His sleep was constantly disturbed at night and he awoke in the morning unrefreshed and tired. He said that for years he had suffered from catarrh in the nose and head, but lately things had become so much worse that he felt sure he would go out of his mind if something was not done for him. This gentleman was a tall, pale liverish looking person with the look of suffering stamped on his face. I ascertained that he had treated himself with washes, snuff, and inhalations, but with little effect, and that he had been under the care of a distinguished physician who assured him that his heart, lungs, and abdominal organs were sound. I found in his present condition nothing that one could lay one's hands on and label as disease. The throat was pale and anæmic the interior of the nose was pale, and the mucous membrane was if anything anæmic. There was ample room for nasal respiration and nothing abnormal or irregular was apparent save one sign which I venture to suggest was the key to the whole situation. On either side of the septum there was the tell tale hollow or groove the exact cast of the lower turbinal body. Beyond this there was nothing to indicate that the nose had been anything but free night or day. Well, with this physical condition of complete freedom of nasal respiration and the absence of anything abnormal with the nose this patient was on the very verge of melancholia from the misery and discomfort of complete nasal occlusion so soon as his head was placed upon the pillow. The functions of the nose were here intermittently performed. For 16 hours the nose was free, for eight hours it was closed. Yet this nocturnal occlusion was quite sufficient to affect and put out of gear all the correlated functions of the nose and to bring the economy almost to a standstill.

An almost exactly similar case was that of a barrister sent to me from Dublin by a member of this association. These are extreme but typical cases and happily, I am glad to say, are few and far between. The commoner forms of intermittent nasal obstruction present symptoms of less severity. In many cases there is only the slight hoarseness and morning cough and difficulty in clearing the throat on rising in the morning. There may only be a tendency to flatulent dyspepsia or distension after meals. The hearing may not be quite so good as it was, and the patient may tell you he thinks he is getting deafer, until he finds out he is suffering from a marked degree of deafness. This is constantly the only symptom of intermittent nasal obstruction. I believe that in intermittent or latent nasal obstruction we have a valid and sufficient explanation for the existence of that large class of slow insidious painless forms of ear trouble known as chronic progressive deafness. Given an occlusion of the nose for eight out of the 24 hours and you have all the factors ready, and able to produce occlusion of the Eustachian tubes congestion of the tympanic cavity, and depression of the drum head and the subsequent physical changes known as sclerosis. This explanation is worthy of your consideration and the more I live and learn the more assured I am of its soundness.

I have on more occasions than one insisted that there is an intimate relation between intermittent nasal obstruction and the affections of the other recesses and extensions of the nose, and the same anatomical and physiological facts that govern the recess of the middle ear apply equally with all the other extensions of the nose. The tympanic cavity and the antrum or frontal sinus are on all fours with each other. They have a common origin their lining membrane is similar and continuous. They are subject to the same variations in air tension and supply and they are subject to the same affections. I have recently exhibited to you a case of frontal sinus trouble where the suppuration was kept up for three years by occlusion of the nostril on the same side from collapse of the wing of the nose and enlargement of the turbinal body. On reducing the turbinal body and supporting the wing the suppuration promptly disappeared. Uncomplicated chronic suppurations of the accessory cavities of the nose are induced and maintained by intermittent obstructions of the nose. This applies equally to the aural accessory cavity.

The obstinate discharges from these cavities that continue sometimes after operations are to be explained when intermittent nasal obstruction is present. We have heard a good deal lately about the etiology and treatment of polypi. My experience is that when these growths are properly removed and the nose is properly ventilated and nocturnal nasal obstruction is prevented they do not return. I have one case which illustrates my meaning perfectly. I operated on a man whom I exhibited in this room as a typical martyr to asthma and who was relieved by clearing his nose from polypi. Well, these growths recurred and required removal off and on for 11 years. In the earlier periods of my treatment I took no account of the fact that he was completely obstructed at night time and yet was free during the day. The asthma was better when the nose was cleared, but returned with the obstruction. Some four or five years ago I operated on both lower turbinal bodies. I have never had occasion to treat him medically since and his nose remains perfectly free from polypi to this day. I believe that intermittent nasal obstruction plays an important part in the production and recurrence of polypi. Much more could I say on this important subject but the time at my disposal will not suffice for a more extended view.

We pass now to the subject of diagnosis. How do we know when intermittent nasal obstruction is present or not? If there is nothing abnormal to be seen in the nose and if the functions of nasal respiration are perfectly and adequately performed, by what signs shall we be able to recognise this form of obstruction? In latent or intermittent nasal obstruction the obstruction, as a rule, occurs at night time when the head is on the pillow and the body is more or less in a horizontal position. When up and about, as in sitting, walking, or standing, there is seldom obstruction except on passing from a cold to a warm atmosphere and sometimes when drinking hot liquids or taking spiced or pungent meals and after alcoholic drinks. In the vertical position of the trunk gravity retains the venous blood in the great vessels of the neck, the chest, and the abdomen. On assuming the horizontal position the blood flows into the veins and sinuses of the head and neck in response to the same force. When sleeping the arteries become smaller in calibre and the veins become larger so that the veins of the head and neck contain relatively more blood. The cavernous tissue and the mucous membrane of the nose become when lax and atonic distended mechanically by the increased intravascular pressure caused by the mere inflowing of blood to these parts The distended turbinal bodies approach the septum on either side and press upon it so vigorously as to form a groove or exact cast of themselves and completely to obliterate the lumen of the nasal chambers. The erectile tissue on the floor and the lower part of the septum helps to complete this. The groove then is to be sought for and is undoubtedly evidence of the condition I am attempting to describe to you. It is, indeed, more than evidence, it is pathognomonic of intermittent nasal obstruction and is the only objective sign that will present itself to you. With subjective symptoms of laryngeal, throat, nose, or ear trouble, and the objective sign I have described to you you have all the evidence you require to make the diagnosis of intermittent nasal obstruction. I place no credence on the answers of patients to the question as to the method of breathing at night. Some, very often the worst cases, will indignantly repudiate the suggestion that they breathe through the mouth at night, yet will in the same breath tell you that they awake with the tongue dry and are always anxious for a cup of tea in the morning.

The subject of treatment will involve much time and consideration and as I feel I have already occupied a large measure of your time and, like yourselves, am anxious and looking forward to the Presidential address, I will postpone the subject of treatment to a more opportune moment. If in the remarks I have made I have given you any suggestions worthy of your acceptance or set you thinking on this important subject I shall be more than amply repaid for the anxiety and labour attendant on this communication.

Harley-street, W.

◆

NOTE ON A CASE OF COMA APPARENTLY DUE TO DISTENSION OF THE BLADDER

BY ROBERT MAIN, L.R.C.P., L R C S. EDIN., M.D. BRUX.

ON Saturday, Jan. 23rd, at 5 30 P.M., I was asked to see a middle-aged man who was said to be in a fit. I found him in bed in a completely unconscious condition, with twitching of the facial muscles, lividity of the face, no eyelid reflex, and stertorous breathing. The only history obtainable was to the effect that he had come from Southend on a visit to a near relative and that at the time of his arrival he appeared to be in good health. He had gone to bed on Friday night perfectly well and intending to keep an appointment on Saturday morning. He had his breakfast in bed about nine o'clock but at that time he had some pains in his back and in a general way did not feel well. He had his dinner in bed about 1.30 P.M. and said he was going to sleep. The symptoms were suggestive of uræmic coma. The chamber utensil, however, was half full of urine which I examined. It only deposited a trace of phosphates on heating and otherwise was normal. In the abdomen there was a fairly hard mass extending up to the umbilicus. I immediately passed a soft indiarubber catheter (No. 6) which entered the bladder with ease and drew off a large quantity of blood and urine. I passed the catheter again at 10 P.M. and withdrew half a pint of smoky urine. The patient did not recover consciousness until 4 A.M. next morning, having therefore been quite unconscious for a period of nearly 11 hours. He has been quite well ever since with the exception of inability to micturate. On Jan. 27th I again examined the urine and found it to be normal with an excess of acidity. There was no stricture or prostatic enlargement.

Finsbury-park, N.

AN UNUSUAL CASE OF SALICYLIC ACID POISONING.

BY J. KENNEDY MATHESON, M B., CH.B. EDIN.,
HOUSE SURGEON, BRADFORD CHILDREN'S HOSPITAL.

A BOY, aged nine years, was admitted in December, 1903, to the wards of the Bradford Children's Hospital under the care of Mr. Isaac Mossop, suffering from extensive erythema iris. Nearly the whole body was affected, the disease being most marked on the lower part of the abdomen and the upper part of the thighs. In many places the bullæ at the margins had broken, leaving masses of scabs, whilst elsewhere their contents were of a purulent nature. Starch poultices were employed for several successive days until all the scabs were removed and then Lassar's paste, a preparation containing salicylic acid, was applied and iodide of potassium was given internally. Marked improvement took place under this treatment. 17 days later the boy began to complain of severe headache and sore-throat; there was also a slight rise of temperature. The symptoms grew worse, the patient's headache becoming very severe. He was sleepless and verging on delirium, calling out about the noises in his ear His temperature went up on successive nights to 103 6° and 104 2° F. The heart's action became weak and irregular. When visiting the wards on the night when the highest temperature occurred I ordered the Lassar's paste to be omitted and put the patient on stimulants. Three days later all the symptoms had disappeared and the boy's general condition was as before.

The interest in this case lies in the mode of introduction of the poison by absorption through the skin. It may serve as a caution against the too prolonged use of this paste which is no doubt very useful in skin affections, especially those of an eczematous type.

Bradford.

THE VERMIFORM APPENDIX ADHERENT IN A HERNIAL SAC AND BY OCCLUDING THE DISTAL PORTION OF THAT SAC LEADING TO THE FORMATION IN IT OF A HYDROCELE.

BY W. P. GOWLAND, M B., B.S. LOND., M.R.C S. ENG.,
SENIOR HOUSE SURGEON TO THE LINCOLN COUNTY HOSPITAL.

A WOMAN, aged 56 years, was admitted to the Lincoln County Hospital with a tense swelling of, about the size of a hen's egg in the right groin. There was no impulse on coughing and the swelling was quite mobile from side to side but was fixed in the line of the inguinal canal. It was first noticed by the patient three weeks before admission and was then about half its present size; a medical man had withdrawn clear fluid with an exploring needle and the diagnosis made was hydrocele of the canal of Nuck.

Operation was performed on August 15th, 1903. The sac was exposed and isolated. Its neck was found to be rather tightly nipped by the pillars of the external abdominal ring and these were incised. The sac containing fluid was then found to be the distal portion of a peritoneal diverticulum, the proximal part of which contained the appendix. The diverticulum was much narrowed at the external abdominal ring and here the appendix was adherent by its apex to the walls of the sac. The appendix was amputated, the sac was ligatured and its distal portion removed, and a radical cure was performed. Recovery was uneventful and the patient has remained well since.

This case seemed worth recording in view of the fact that according to Erichsen a true hydrocele of a hernial sac—i.e., an accumulation of fluid in a part of the sac that has been cut off from all communication with the cavity of the peritoneum—is somewhat rare. Further, in THE LANCET of Jan. 30th, 1904, p. 296, under the heading of "Clinical Notes," a similar condition was described, though there the appendix itself was mistaken for a hydrocele.

I am indebted to Dr. W. A. Carline, senior surgeon to the hospital, for permission to publish this case

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Anæmia Pseudo-leukæmica Infantum.

A MEETING of this society was held on Feb. 9th, Mr. ALFRED WILLETT, the President, being in the chair.

Dr. J. H. DRYSDALE and Dr. J. H. THURSFIELD communicated a paper on Anæmia Pseudo leukæmica Infantum of von Jaksch. They said that in the year 1889 von Jaksch described a type of anæmia occurring in infancy which he believed to be different from any of the recognised varieties; he accordingly proposed for it the name by which it had been known since upon the continent, though in this country it had been more usually called the splenic anæmia of infants. The chief interest in connexion with the disease had centred in the controversy whether it was to be regarded as a disease *sui generis* or as a mere complication or sequel of any severe anæmia occurring in infancy. Dr. Drysdale and Dr. Thursfield held to the first opinion and endeavoured to set forth the reasons of their belief. A short *résumé* of the clinical features of the disease was followed by a more detailed account of the symptoms which appeared to them to be characteristic of the complaint; briefly enumerated they were a profound anæmia of gradual onset and chronic duration; an enlargement of the spleen, such as was met with in no other form of anæmia of infancy except in the rare cases of true myelogenic leukæmia; a tendency to petechial hæmorrhages; and a constant and peculiar change in the condition of the blood. The precise changes in the blood were explained and summarised on the basis of a considerable number of examinations made in cases of this type and the results were contrasted with those obtained from infants suffering from severe anæmias of other types. Lastly, the relations of this disease with some of the other anæmias, which were commonly met with in infancy, were considered and stress was laid on the fact that this type had never under observation developed from any of the other varieties. Tables were appended giving (1) a statement of the cases on which the paper was based; (2) a detailed account of the blood examinations; and (3) a *résumé* of the blood examinations made in certain other anæmic conditions of infancy.

Dr. R. HUTCHISON said that he wished he was as certain as Dr. Drysdale and Dr. Thursfield seemed to be that the disease was *sui generis*. He doubted if they were justified in regarding the disease as a definite entity whilst the pathology remained so uncertain. The changes in the blood could not be regarded as forming a feature distinctive of this disease, for in severe rickets and in severe congenital syphilis changes in the blood were met with which approximated closely to the condition found in this disease and it was impossible to mark off the disease so sharply as Dr. Drysdale and Dr. Thursfield made out. He thought that the anæmia was probably due to insufficient and incorrect feeding and the rickets which not infrequently accompanied the disease was due to the same cause. He next dealt with the relation of this disease to true leukæmia and stated that in his opinion there were not more than two or three cases reported of true leukæmia in children below the age of two years. He said that there was nothing characteristic in the morbid anatomy and exactly similar changes were found in the organs in fatal cases of rickets. Even the bone marrow presented no characteristic change. He was of opinion that this disease might be a secondary anæmia, possibly due to some specific cause which had yet to be discovered.

Dr. E. P. BAUMANN said that on the main issue—namely, the question of the existence of this disease as an entity—he was in complete agreement with the view put forward in the paper. In other points, however, he differed from some of the conclusions. In the first place, he was of opinion that the title anæmia pseudo-leukæmica infantum was cumbersome and unnecessary. Pseudo leukæmia was the term by which Hodgkin's disease was commonly known abroad. Now there was no apparent connexion between Hodgkin's disease and the disease under discussion. Nor did this disease resemble very closely the condition of leukæmia. He was therefore inclined to adhere to the simple name of splenic anæmia of infants. He was surprised at the number of cases of recovery (from 60 to 70 per cent. according to the table). Of seven cases which he had had the opportunity of observing during the last two years at the Hospital for Sick Children, Great Ormond-street, six patients died in hospital and one went out improved. Among out-patients, where the cases would not all be severe, the mortality would doubtless be lower. Nevertheless, allowing for this he still believed the disease to be a very fatal one. Turning to the consideration of the condition of the blood Dr. Drysdale and Dr. Thursfield obtained an average leucocyte count of 24,100 and their table showed figures reaching in some instances to more than 50,000 leucocytes per cubic millimetre. In his own case an average of from 12,000 to 14,000 per cubic millimetre was present. The largest number found in any case was 20,000. Dr. Drysdale and Dr. Thursfield seemed to attach little importance to alterations in the shape and staining reactions of the blood corpuscles. It had always appeared to him that this alteration in shape formed one of the most striking features of the disease. In some cases the polymorphous character of the blood corpuscles had been so striking as to simulate pernicious anæmia. As regards the etiology of the disease he had noted the large incidence of splenic anæmia among the children of Polish Jews. Syphilis existed in a far larger number of his cases than in those reported in the paper. In only one case could a specific taint be definitely excluded; in three cases the existence of syphilis was

rickets. He, however, agreed with Dr. Drysdale and Dr. Thursfield that splenic anæmia was a disease *sui generis* and that it could not be considered to be secondary to any other disease.

Dr. G. NEWTON PITT suggested that the condition of the blood was evidence of a reaction against some toxic condition. In the cases reported there were periods in which the leucocytosis varied and this seemed to him to point to a process of reaction rather than to a specific infection. He suggested that the disease might bear some relation to splenic anæmia of the adult—Banti's disease.

Dr. NORMAN MOORE said that Sir William Jenner had always taught that an enlarged spleen was a common characteristic of rickets and he thought it probable that the enlargement of the spleen and the rickets were produced by the same cause.

Dr. DRYSDALE, in reply, said that he considered that the clinical features of the disease, together with the condition of the blood, formed a definite picture which entitled the disease to be regarded as an entity. He did not consider syphilis as a cause of the disease. Syphilis was present in a certain number of cases but in others it could be definitely excluded. He did not think that the disease in any way [illegible] anæmia of the adult [illegible] en proved [illegible] form of [illegible] our of the [illegible]

MEDICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Feb. 8th, Dr. CHARLES E. BEEVOR, one of the Vice-Presidents, being in the chair.

Mr. W. G. SPENCER exhibited (for Dr. F. DE HAVILLAND HALL) a case of Ascites occurring in a married woman, aged 30 years. Dropsy first appeared four years ago after a confinement and she had been tapped ten times in the Westminster Hospital. In December, 1902, Mr. Spencer opened the abdomen and stitched the omentum to the anterior abdominal wall. A month later the patient left the hospital free from dropsy but in about six weeks fluid began to collect again. On March 4th, 1903, she was readmitted into the hospital with a large amount of ascites and great œdema of the legs. A soft systolic murmur was audible at the cardiac apex. The urine contained a small quantity of albumin. On March 10th Mr. Spencer made an incision through the old scar, the omentum was pushed aside, a large amount of fluid was evacuated, and the cavity was left to drain. On April 2nd the operation wound was nearly healed. The patient was discharged on April 25th free from dropsy and had re-married since. At the present time there were slight œdema of the ankles and a systolic and a presystolic murmur at the apex.—The case was discussed by Dr. C. THEODORE WILLIAMS, Dr. ALEXANDER MORISON, and Dr. H. A. CALEY.

Dr. V. WARREN LOW showed a case of Extreme Atrophy of both Testicles due to Syphilis in a man, aged 39 years, who had had a chancre followed by rash 12 years ago. He did not notice the diminished size of his testicles till his attention was drawn to it at the hospital some 12 months ago. He was then suffering from tertiary syphilitic ulcers on both legs and for these he had been under treatment off and on for a year. The right testicle could still be felt and was of about the size of a horse bean. There were certain symptoms pointing to incipient tabes dorsalis.

Dr. F. PARKES WEBER exhibited a case of Neurotic Alopecia of the Scalp and Face after Shock. The patient was a man, aged 39 years, who had lost both eyebrows and eyelashes and almost all the hair of his scalp and that of the lower part of the face. There was a history of a mental shock in August, 1902, and of hæmoptysis in November of the same year, and the hair had commenced to fall off in the following March, the eyebrows being affected only for four or five weeks.—The case was discussed by Dr. ALFRED EDDOWES and Mr. G. PERNET who did not agree that the origin of the baldness was neurotic.

Mr. RICHARD LAKE exhibited a case of Menière's Disease in a patient, aged 21 years, who presented four symptoms—viz., deafness, tinnitus, vertigo, and sickness. The tinnitus had been continuous and hissing in character. The attacks of vertigo and sickness varied in frequency and intensity. They had been more frequent and more severe for the last two years. Actual vomiting did not always occur with, and never relieved, the vertiginous attacks. The patient felt inclined mostly to fall forwards or backwards and objects had no regular plane in which they rotated. Several drugs had been tried but had been found useless.

Dr. CAREY F. COOMBS (introduced by Dr. CALEY) exhibited a case of Cerebellar Disease with unusual features. The patient was a boy, aged 13 years, who came under the care of Dr. Robert Maguire at St. Mary's Hospital in October, 1903, for inability to walk or to stand. This had come on about three weeks before suddenly and without any preceding headache or other symptoms. The only other thing noticed by his friends was that his speech was altered in character. On Oct. 20th it was noted that the gait was of a reeling cerebellar type, the patient falling more to the right. The hands were ataxic and there were tremor of the eyelids and slight nystagmus; the pupils and optic discs were normal. The knee jerks were increased and there was plantar extensor response on both sides. The sudden onset and the gradual improvement under iodide of potassium were the most notable features.—The case was discussed by Dr. BEEVOR and Dr. WILFRED HARRIS who suggested thrombosis as a probable diagnosis.

Mr. G. E. GASK exhibited a case of Ossification of Tendons of the Leg in a man, aged 45 years. Three weeks before the patient had experienced some pain in the left leg and thigh which he attributed to rheumatism. On rubbing his leg he discovered a hard swelling on the outer side of the left leg, three and a half inches long, apparently in the peroneus muscle. There was no history of injury. The skiagram showed a shadow of a dense substance unconnected with the fibula.—Mr. EDMUND OWEN and Dr. CALEY discussed the condition and mentioned other cases.

Dr. J. KEOGH MURPHY exhibited a case of Meningocele (?) through the Left Parietal Foramen. The patient, aged three months, was otherwise a healthy infant. The swelling on the head was noticed from birth and was said to increase during straining. On Dec. 14th, 1903, there was noted a nævoid umbilicated swelling half an inch square to the left of the middle line, and this was irreducible. On Jan. 4th, 1904, the swelling could be entirely reduced and the bony edge felt. On Jan. 25th there was a slight increase in size but it was still easily reducible. There were no cerebral symptoms.—The case was discussed by Mr. H. S. COLLIER who thought the lesion might be a dermoid cyst.

Dr. MURPHY also brought forward an infant exhibiting Congenital Deformities.

Mr. H. J. WARING showed a case of Repair of Traumatic Deficiency in the Skull by a Gold Plate. The patient was a soldier, aged 22 years, who was shot in the left occipital region on Jan. 28th, 1901, by Boers outside Kimberley. He was said to have been unconscious for three weeks and afterwards remained in a Boer hospital for five months. He was subsequently invalided home. A circular hole two inches in diameter was then found in the left occipital region of the skull and through it protruded a soft fluctuating swelling. The patient was subject to epileptiform seizures. An exploratory operation was performed and a cyst of the arachnoid, which was found bulging through the aperture, was removed. The aperture in the skull was closed by placing a circular gold plate, three inches in diameter, over the hole and fixing it with gold nails, over which the periosteum was sutured. The patient made a quick recovery and had had no further cranial symptoms.

Mr. OWEN showed a case of Ischæmic Paralysis in a man, aged 38 years, who about two years ago had had the upper end of his right ulna fractured in two places by a blow from the spoke of an iron fly-wheel. Two hours subsequently the arm had been put up in a very tight plaster-of-Paris bandage which was passed chiefly round the elbow region. Next day the lower part of the forearm and the hand were swollen and some blebs had appeared and the bandage was then removed. The forearm was now much wasted, the flexor muscles being indurated and rigid. The forearm was pronated and fixed. Sensation was greatly impaired in the hand. The metacarpal bones stood out in strong relief because of the complete atrophy of the interossei and other muscles. Though this condition was unfortunately often met with in children it was rare in the adult. Mr. Owen had, however, shown a similar case at this society about three years ago. The condition was probably due to the tightness of the bandage which had kept the muscles anæmic during the night and had so injured them that a myositis had supervened and this had been followed by atrophy and fibrosis. No doubt the nerves of the forearm had also shared in the pathological disturbance. The outlook as to treatment seemed extremely unpromising.—Dr. WILFRED HARRIS and Dr. BEEVOR both expressed the view that injury to the nerves of the forearm would sufficiently account for the condition without myositis or anæmia of the muscles.

PATHOLOGICAL SOCIETY OF LONDON.

The Organisms of Monkey Malaria and Sleeping Sickness.—Agglutination.—Iron Hæmatoxylin Staining.

A MEETING of this society was held at the Lister Institute on Feb. 2nd, Sir JOHN BURDON SANDERSON, the President, being in the chair.

Mr. H. G. PLIMMER showed the Organisms of Monkey Malaria and Sleeping Sickness under high magnification. The latter organism he demonstrated under a magnification of 5000 diameters. He showed the arrangement of light and lenses necessary for obtaining suitable illumination for such magnification.

Mr. J. ANDERSON CRAW read a paper on the Mechanism of Agglutination. He said that in view of the large number of hypotheses advanced to account for the phenomenon of agglutination and the purely qualitative nature of the observations advanced in support of the same it was considered advisable to investigate the matter from a quantitative and physico-chemical standpoint. Only after a thorough investigation of the physical and chemical actions involved could a definite conclusion regarding the value of agglutination in diagnosis be arrived at. Recently views which he considered to be quite void of foundation had been advanced to account for the mechanism of this reaction and it seemed justifiable to submit these and other hypotheses to the test of criticism and experiment on a physico chemical basis, as an article by Dr. A. E. Wright in THE LANCET[1] lately showed how difficult it was to grasp the significance of the physical forces involved. Gruber's hypothesis that a glutinous substance "glabrificin" was absorbed by the bacilli from the serum forming small adhesive prominences on their membranes which caused the cells to adhere on contact was insufficient, for dispersed non-motile bacilli agglutinated and staining failed to show any abnormality of the membrane. Pfeiffer's hypothesis that the specific serum substance caused a vital paralysis was disposed of by the facts that after absorption of the specific substance the cells remained motile and the addition of salts caused agglutination, but reproduction did not cease; again dead bacilli and fragments of cell membrane agglutinated. Paltauf's hypothesis that a specific precipitate was produced in the fluid which during flocculation mechanically carried the bacilli with it was disproved by the agglutination of washed and young bacilli in media which gave no precipitate and also by the formation of a specific precipitate without simultaneous agglutination. Nicolle's hypothesis eluded the objections to Paltauf's hypothesis by assuming the specific precipitate to be produced in the membrane, but the latter was supposed to dilate and to become glutinous, which was open to the objections raised against Gruber's hypothesis. Dineur considered the *cilia to be chiefly instrumental in agglutination, they became glutinous and adhered, but cells without cilia agglutinated.* The Emmerich-Löwe view that agglutination was the first stage of the bacteriolytic action of enzymes was discredited by the partition of agglutinin between medium and cell, by the specific nature of the agglutinins, and by agglutination brought about by chemical agents of non-enzymic character; again the bactericidal enzymes might be destroyed by temperatures at which the agglutinins remained unaffected Duclaux supposed that the bacilli ejected a coagulable substance which was precipitated by a coagulating enzyme, *the precipitate carrying the bacilli mechanically together.* [illegible]

[illegible] of common salt during agglutination and concluded that Bordet's hypothesis could not be maintained. The important *work of Joos could, however, be interpreted in a manner distinctly supporting the fundamental principles of Bordet's* hypothesis. Joos's admirable experiments were mostly qualitative; exact quantitative measurements were now in progress at the Lister Institute. If dialysed serum was added to dialysed bacilli the specific substance agglutinin was found but the cells remained motile and no agglutination took place. The addition of a "trace" of salt caused agglutination. Joos considered that the agglutinable substance formed a soluble compound with the agglutinin and this was precipitated by such a small quantity of salt that it must be assumed *that the latter* reacted chemically. From the facts that salt entered into the compound agglutinable substance, agglutini- [illegible] took place when bacilli containin [illegible] placed in distilled water he (Jo [illegible] was chemically active and not [illegible] conclusion could not be admitted, as all precipitated albuminoids absorbed the precipitating salts and salt in the second case would diffuse into the media. It was immaterial whether the salt formed a chemical compound or not; the action was probably one resembling *solution.* The second phase of agglutination, the more difficult to explain, could best be investigated by a study of the laws governing sedimentation and precipitation. The first phase had to a certain degree been admirably probed by Eisenberg and Volk, a lucid interpretation of their results being given by Arrhenius. The agglutinin distributed itself between the medium and the bacilli, much as iodine was distributed or partitioned between water and carbon disulphide. In the latter case the ratio of iodine concentration in water to the iodine concentration in carbon disulphide was constant, no matter how much iodine was added. Similarly a constant partition coefficient, but of a more complex nature, could be obtained for the partition or division of agglutinin between aqueous medium and organisms. Arrhenius concluded that the bound and free agglutinin molecules had a different number of parts in the ratio of 2 to 3. It was from results obtained in conjunction with Dr. Allan Macfadyen at the Lister Institute highly probable that the partition coefficient for agglutinin between medium and organism varied for different parts of the cell, flagella, membrane, and cell juice and quantitative experiments in this direction were in progress. As regards the second phase of agglutina- [illegible] current ideas on this subject had been arrived at. Bodländer found that a suspension of kaolin in distilled water was rapidly sedimented by electrolytes. Joly's experiments on [illegible] the alkaline earths [illegible] the monovalent [illegible] had been made to determine the influence of electrolytically dissociated or ionised substances on colloidal solutions. Hardy measured the concentration of hydrochloric, nitric, sulphuric, oxalic, and citric acids necessary to precipitate colloidal iron oxide to the same degree of turbidity in the same time and calculating from his results one citric acid ion had about the same effect as 740 chlorine ions, while one sulphate ion had [illegible] chlorine ions. From the facts that the [illegible] uric acid di- [illegible] it had been [illegible] that the number of electric charges on the ion deter- [illegible] ng value. Bredig had [illegible] mena of sedimentation, [illegible] the action of enzymes, [illegible] pillary phenomena to [illegible] hypothesis of electric double envelopes. According to this hypothesis the layer between colloidal particle and aqueous solution had a "natural" surface tension diminished by the electric repulsion of any positive and negative ions or electrons that happened to form part of the surface of separation. When the "natural" potential difference of a colloid against an aqueous medium was neutralised by the addition of an electrolyte the surface tension of the particle should become a maximum. This was highly improbable Current views were founded on the electro-capillary phenomena of the Lippmann electrometer. From a two years' study of the influence of electrolytes and non-electrolytes on the surface tension and potential difference of mercury against aqueous solutions he had demonstrated that the Helmholtz hypothesis was untenable. Mercury in certain solutions might have a maximum surface tension and at the same time be highly charged with respect to the aqueous phase. Similarly by the addition of non electrolytes to suspensions it had been found that surface tension effects played a more important rôle than electrical potential differences. Amyl alcohol, butyric acid, camphor ethyl benzoate, and other substances influencing the surface tension of water showed marked and similar effects in accelerating sedimentation, precipitation, and agglutination. Ions had all the properties of ordinary chemical units in addition to their electrical effects and the *surface* tension effect of an ion might have no direct relation to its electrical effect. Friedberger showed that grape sugar could induce the second phase of agglutination and electrical effects in this and other cases were practically eliminated. In conclusion, the first phase of agglutination was in many respects similar to solution absorption or staining and the second phase an absorption and surface tension effect.

Dr. A. PAINE read a communication the title of which was a New Method of Staining with Iron Hæmatoxylin. His *object* was to bring forward a new method of using iron hæmatoxylin as a chromatic and cytoplasmic stain, but before doing so he briefly referred to the processes of Benda and Heidenhain, which by acknowledged authorities were the best of their kind. Iron hæmatoxylin belonged to the so-called hæmatin lakes. There were three principal lakes of hæmatoxylin, those it formed with copper, chromium, and iron. Of these only the iron compound had remained in general use and for the purposes of histological research it

LIVERPOOL MEDICAL INSTITUTION.

Hot-air Cautery.—Poisoning by Antimony and Lead.—Intravesical Separation of the Urine.—Puerperal Septicæmia.

A MEETING of this society was held on Feb. 4th, Dr. JAMES BARR, the President, being in the chair.

Dr. K. A. GROSSMANN gave a short account of the Hot-air Cautery introduced into surgery by Dr. Hollander of Berlin and showed a modification of the instrument adapted for [illegible] employed it with [illegible] elid, in corneal [illegible] it particularly valuable in cases of conical cornea. The different degrees of heat could be easily regulated and he had found the results superior to those obtained by the actual cautery.

Dr. LESLIE ROBERTS exhibited a patient, a compositor by occupation, suffering from Chronic Poisoning by Antimony and Lead. The symptoms complained of were sweating, tenderness of the palms of the hands and soles of the feet, and pains in the muscles of the arms and back. The patient had been forced to give up work on account of the tenderness of the fingers. The palms were of a pinkish-red colour and drenched with perspiration. Scattered all over the palms were small, flat, smooth papules. Microscopic examination of the skin showed the rete to be hypertrophied, the sweat ducts to be much dilated, and the capillaries to be congested. The condition of the palms was not to be distinguished from that seen in some forms of arsenical poisoning. The linotype alloy was composed of tin, antimony, and lead. The patient's urine was free from albumin but contained lead, to which metal the tremors and muscular weakness might be attributed. He had not suffered from colic. The plumbism seemed to have been modified by the presence of antimony.

Mr. ROBERT BICKERSTETH read a note on the Intravesical Separation of the Urine coming from the Right and Left Ureters as an Aid to Diagnosis in Surgical Diseases of the Kidneys. After contrasting the older methods with the only alternative—namely, catheterisation of the ureters—he showed the "separator" introduced by Dr. George Luys of Paris. He said that he had used this instrument for the last six months and he described cases and showed specimens of separated right and left urines which proved the method to be of the greatest utility. During the examination it was neither necessary nor advisable to administer a general anæsthetic, for after the introduction of the instrument the patient should be placed in the sitting posture.—Mr. F. T. PAUL related several cases under his care in which Mr. Bickersteth had by means of the "separator" furnished him with most valuable information.—Mr. K. W. MONSARRAT had been greatly impressed with the value of the instrument in a case under his care that Mr. Bickersteth had examined.

Dr. NATHAN RAW read a paper on the Pathology, Bacteriology, and Treatment of Puerperal Septicæmia with special reference to the value of antistreptococcic serum, based on an observation of 61 cases in the Mill-road Infirmary, Liverpool. He said that the disease in no way differed either in origin or in symptoms from several other infective and septic processes and was not peculiar to the lying-in state. The micro-organisms found in his series were as follows: streptococcus pyogenes in 27 cases; staphylococcus aureus in six cases; mixed infections in 13 cases; bacillus coli communis in 11 cases; and the diphtheria bacillus in one case. In three cases there was no growth of organisms. Before using antistreptococcic serum it was essential to demonstrate beyond doubt that the infection was streptococcic. This could readily be done by staining a little of the secretion from the uterus. In advanced cases the blood might be used for this purpose but it was difficult to recover streptococci from the blood unless it was taken from a vein in large quantity, say, five cubic centimetres, and then they were not always found. His experience went to show that the serum was of the greatest possible value in pure streptococcic infections if employed early in the disease. The dose he employed was 20 cubic centimetres twice or thrice daily and continued for several days. He had never known any harm or bad symptom to arise from its use if obtained from a trustworthy manufacturer and with a bacteriological guarantee of its purity. In the total number of 61 cases under observation there were 32 recoveries and 29 deaths, giving a death-rate of 48 per cent. The patients treated with serum were 37 in number with 24 recoveries and 13 deaths, giving a death-rate of 36 per cent. The number treated without serum was 24 with eight recoveries and 16 deaths, giving a death-rate of 60 per cent. Several of the patients in the last group were admitted to hospital in an advanced stage of the disease when obviously no treatment would be of avail.—Dr. J. E. GEMMELL said that the presence of streptococci in the lochial discharges was not sufficient indication for the use of the serum, for it was known that examinations of normal vaginal discharges and of lochial discharges during a normal puerperium had yielded streptococci.—Dr. HENRY BRIGGS said that he had frequently used the serum but had grave doubts as to its real utility.—Dr. LLEWELLYN A. MORGAN, Dr. E. T. DAVIES, Dr. T. B. GRIMSDALE, Dr. F. B. O'FLAHERTY, and Dr. A. S. F. GRÜNBAUM also took part in the discussion.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Glycogen in the Blood.—General Streptothrix Infection.—Glaucoma.

A MEETING of this society was held on Feb. 3rd, Professor JOHN CHIENE, the President, being in the chair.

Dr. LOVELL GULLAND read a paper on the Glycogen Reaction in the Blood. He described the nature of the glycogen reaction and the method of applying it by staining the granules with iodine. He discussed the conditions under which glycogen was present in the blood, its pathological relationships, and its connexion with leucocytosis.

Dr. STUART MCDONALD read a paper on a case of General Streptothrix Infection. The patient, who was a woman, died in the Royal Infirmary about 18 months ago. She exhibited some obscure nervous symptoms on admission though she had been ailing for some months from cough and there had been a more recent acute illness of some five weeks' duration with definite pleurisy. It was impossible to get a proper history from her or to make a complete physical examination; she gradually became comatose and died two days after admission. At the post-mortem examination numerous small abscesses were found in the brain and kidneys; there were inflammatory deposits in the heart wall [illegible] which [illegible] tuber- [illegible] A typical streptothrix was found in all the lesions and pure cultures were obtained from the kidney. These cultures had been kept alive ever since and the organism studied on various media. It appeared to be either identical with Eppinger's streptothrix or closely related to it. The cultures were found to be definitely pathogenic for rabbits and [illegible] though rats and mice were apparently immune. [illegible] appearance in old cultures of [illegible] were acid fast and alcohol fast after being stained with Ziehl-Neelsen's carbol fuchsin and which in some cases strongly resembled tubercle bacilli.

Dr. J. V. PATERSON read a paper on Glaucoma and the Glaucoma Theories. He described the anatomy of the parts of the eye connected with the secretion and elimination of the aqueous humour and the experimental work and methods recently employed to determine the source of the aqueous, the normal rate of secretion, and the paths by which fluid leaves the eye. Leber's conclusions as to the rate of flow during life were given, as were also the questions of the outflow by way of the nerve, of the permeability of the hyaloid, and of the kind of communication existing between the anterior chamber and the veins. In the monkey's eye [illegible] Dr. Paterson had found that Chinese [illegible] chamber penetrated freely into [illegible] as into the canal of Schlemm and the veins at the [illegible] angle. For estimating the amount of flow through the eyeball under different conditions he had employed an apparatus somewhat modified from that used by Priestley Smith, the graduated tube carrying the air-bubble being of finer calibre so that the readings could be taken every minute. The question of intraocular tension was then discussed and its relation to the blood pressure, arterial and venous, was considered. Secondary glaucoma was usually due to mechanical causes obstructing the flow of aqueous humour. Cases to illustrate this were described—e.g., iris bombé, iris prolapse, traumatic cataract, cyclitis, and intraocular tumours. Primary glaucoma was much more difficult to explain and eyes were removed only in the later stages of the disease when it was difficult to determine the priority and importance of the lesions found. The lesions associated with advanced glaucoma, on which most stress had been laid, were: (1) cupping of the disc with accompanying optic atrophy; (2) closure of the filtration angle; and (3) changes in the intraocular blood-vessels. Dr. Paterson discussed the theories of von Graefe, Knies, Birnbacher, Fuchs, Abadie, and Panas to explain the occurrence of glaucoma. Although no adequate explanation of primary glaucoma had yet been offered he was inclined to think that a theory of retention with blocking of the filtration angle was the one which best explained the acuter forms of the disease. The more chronic forms of glaucoma probably depended on local and general vascular changes which might influence the blood pressure and the intraocular secretion. Priestley Smith's theory was also criticised and Dr. Paterson said that he had never seen any pathological evidence that the circumlental space had been blocked in any of the series of glaucomatous eyes which he had examined.—Dr. BERRY and Dr. GEORGE MACKAY discussed the paper.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY.

Pelvic Fascia.—Pawlow's Gastric Fistula.—Blood Films.

A MEETING of this section was held on Jan. 29th, Dr. E. H. TAYLOR, the President, being in the chair.

Dr. R. ATKINSON STONEY read a paper on the Anatomy of the Pelvic Fascia, with special reference to its surgical importance. He described a new method of demonstrating the connexions of the visceral pelvic fascia by hardening the subject in formalin and then having made a mesial section of the pelvis the prostate and bladder were dissected out of their fascial envelopes. By means of specimens dissected in this way and drawings and diagrams made from them he showed that the visceral layer of pelvic fascia, instead of dividing into three layers as usually described, really gave off three complete sheaths, two in a downward direction surrounding the prostate and rectum and one in an upward direction surrounding the bladder, and that each of these was complete in itself and in no place did one layer of fascia enter into the formation of more than one of these three sheaths. He also pointed out that the visceral layer of pelvic fascia met the urogenital apparatus at the vesico-prostatic junction and the alimentary canal at the junction of the rectum and anal canal.—Sir THOMAS MYLES, the PRESIDENT, Professor ALEXANDER FRASER, and Professor A. F. DIXON took part in the discussion.

Dr. HAROLD PRINGLE exhibited a dog on which he had performed Pawlow's Gastric Fistula Operation. The object of the operation was to produce a stomach pouch which was made to open on the surface, while the remainder of the stomach was left to perform its digestive function as usual. The pouch was formed in such a manner as to retain its nervous connexions intact. Some lantern slides were shown giving the results of experiments which proved that the juice secreted by the stomach pouch varied in amount and rate of secretion, corresponding with the results already published by Pawlow.

Dr. HENRY M. JOHNSTON gave a demonstration on the making of Blood Films by a new method, the apparatus for which was very simple. He also showed specimens of films stained and unstained.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—A meeting of this society was held on Jan. 15th, Dr. J. Porter Parkinson being in the chair.—Dr. G. E. C. Pritchard showed a case of Transposition of the Viscera in a girl, aged 12 years, the heart, the liver, the stomach, and the spleen being transposed. The child had been delicate since birth and at one time had been treated for enlargement of the spleen owing to the liver having been mistaken for that organ. She was also deficient mentally and it was intended to have a skiagram taken for the purpose of seeing whether the aortic arch was on the right side.—Dr. Pritchard also showed a case of Congenital Absence of the Left Arm in a girl, aged 15 years. The stump ended about two inches below the elbow in a small excrescence which presented the appearance of a rudimentary thumb provided with a nail.—Dr. C. O. Hawthorne said that he had seen at least two such cases in which there were processes that might be called digits.—Mr. A. H. Tubby showed a case of Sarcoma with Secondary Deposits in a boy aged two and three-quarter years. Seven weeks previously the child received a knock on the left leg and soon afterwards the mother noticed a swelling there which was poulticed. Three weeks ago he was again struck on the same leg and also fell striking his head. A swelling on the head formed soon afterwards. He now presented a definite tumour over the left leg attached to the fibula and a smaller tumour over the right parietal bone. The left inguinal and iliac glands formed a large adherent mass but were not tender. Mr. Tubby commented on the direct connexion of the growths with an injury. In a paper published in THE LANCET some years ago he pointed out the direct relation of traumatism to sarcoma of bone and he thought that this was now generally accepted. Owing to the implication of the glands he did not consider that any operative treatment was available.—Mr. Tubby also showed a case of Congenital Dislocation of the Fifth Cervical Vertebra in an infant, aged three months. The deformity was noticed the day after birth, the confinement having been a normal one. No symptoms had been observed until the previous week when vomiting came on and had occurred several times a day. At the base of the neck there was a sharp bony prominence which corresponded to the fifth cervical vertebra. The summit of this process was formed by the left articular process and the spinous process could be felt to the right of it and not so prominent. There was also congenital scoliosis, the curve being to the right in the dorsal region and to the left in the lumbar. There were no evidences of paralysis. Mr. Tubby proposed to make an attempt to reduce the dislocation by traction and manipulation but thought that as three months had elapsed the prospect of cure was not good.—Mr. J. Howell Evans suggested that there was an absence of half the fourth cervical vertebra and that the marked prominence felt to the left of the middle line was the superior articular portion of the lamina of the fifth cervical vertebra, which was unopposed. The small projection which could be felt almost in the middle line corresponded to the spinous process of the same vertebra. The scoliosis would be the result of the defective vertebra.—Mr. Howell Evans read a paper on the Relation of certain Extracranial and Intracranial Hæmorrhages in the Newly Born. He considered that these hæmorrhages were dependent partly on an irregularity in the moulding of the fœtal head, this irregularity arising from the presence of accessory sutures in the situations where certain extracranial vessels anastomose with the intracranial vessels; another factor was probably the rise of blood pressure which occurred during the reactionary period when the child was recovering from the birth trauma. These hæmorrhages occurred in non-instrumental labours and as frequently in breech as in vertex presentations, and with approximately the same frequency as the accessory sutures he referred to. Selecting the parietal bones as examples he said that when a parietal bone was developed from two centres of ossification there was left a small space extending from the situation of the parietal foramen to the sagittal suture. At the parietal foramen the occipital artery communicated with the middle meningeal artery and the occipital vein directly or indirectly with the superior longitudinal sinus. In a normal fœtal skull these vessels were secure from injury, but when the accessory sutures were present irregular moulding occurred at them and the vessels were lacerated.—Dr. G. A. Sutherland said that cases described as birth palsies were met with in which the labour was normal, neither too prolonged nor too rapid, and it was difficult to understand how such cases were explained by the ordinary pressure theory.—Dr. Hawthorne said that intracranial hæmorrhages occurred in cases which had not been subjected to any undue pressure and even in infants born at the seventh month.—Dr. W. C. Chaffey (Brighton) read a paper on the sequel of a case of Extreme Wasting which had been shown at a meeting of the society in July,

1903. The patient was a boy, aged ten years, who was extremely wasted, refused all solid food, but drank two and a half pints of milk daily and presented no objective signs of cerebral disease. The case had been regarded by most of the members as one of hysteria. In October he developed bed-sores, had attacks of headache with screaming, and tonic contractions appeared in the extremities. These and other symptoms led to a diagnosis of tumor cerebri or meningitis. At the necropsy there was found to be chronic meningitis, chronic hydrocephalus, and an endothelial tumour of about the size of a walnut attached lightly to the posterior aspect of the right optic thalamus. Dr. Chaffey commented on the rarity of endothelioma as a cerebral tumour. He thought that the growth of the endothelioma might have been excited by an injury sustained by the boy in the school playground some twelve months before his death.

MIDLAND MEDICAL SOCIETY.—A meeting of this society was held at the Medical Institute, Birmingham, on Feb. 3rd, the chair being taken by Dr. R. Saundby.—Mr. W. Billington showed a case of recovery after operation for Cerebral Abscess following upon prolonged otitis media. The patient was a man, aged 27 years, who for many years had had a chronic purulent discharge from both ears. Three weeks before operation he began to suffer from pains in the head. He then had a "fit" while at work, became drowsy and stupid, and presented evidences of intracranial pressure. These increased and at the time of operation the patient was deeply comatose with Cheyne-Stokes respiration. The skull was trephined without anæsthesia and a large abscess containing two ounces of fœtid pus was discovered in the left temporo sphenoidal lobe. This was opened and drained. A week later Stacke's operation was performed on the left side. The patient made an uneventful recovery and two months later he was quite well and back at work. His hearing was distinctly good, a watch being heard at a distance of six inches from the left ear, and he suffered from no mental or physical disablement.—Mr. George Heaton showed a man who had recovered after complete suppression of urine from impacted calculi for a period of eight and a half days. He was 40 years of age and had had occasional attacks of obscure lumbar pain for 15 years. Three months previously he had a severe attack of renal colic with hæmaturia. This was followed by the passage of 20 small calculi. Urinary suppression took place quite suddenly four days before his admission to hospital. It was ushered in with severe abdominal pain which soon passed off. During eight and a half days while he was under observation absolutely no urine was passed or was found in his bladder. Throughout this period he showed no uræmic symptoms whatever until the seventh day, when he began to suffer from muscular tremors and became slightly delirious. There was no vomiting or perspiration or pain and there was no loss of consciousness. An exploratory operation was performed in the left loin but owing to the patient's great size the kidney could only just be reached with great difficulty and appeared to be atrophied. On the ninth day the urinary flow suddenly returned. He passed during the next ten days a very large quantity of urine—173, 178, 136, and 126 ounces being passed on successive days. The urine was pale and clear and the specific gravity was 1008; it contained only a trace of albumin. A few weeks afterwards he passed three small calculi. At the present time he was back at work and was in his usual health. Mr. Heaton was disposed to think that the left kidney—the one explored—had been rendered functionless by old disease and that the obstruction had now taken place in the right ureter or pelvis of the right kidney. The man was enormously stout and it was quite impossible to feel any tumour through the parietes.—Dr. W. D. Lawrie showed a case of Paralysis of both Lower Extremities in a boy due to Acute Anterior Poliomyelitis. The point of interest connected with this case was the ingenious method the patient had of interlocking his legs and moving about with a swinging motion supported on his hands. He could in this way mount and descend from a chair.—Dr. J. D. Stanley showed (for Dr. S. H. Perry) a case of Favus in a boy eight years of age. The disease had been present for six years. It was pointed out that favus is rare in Birmingham. Dr. Perry had made careful microscopic examination of the parasite.—Dr. O. J. Kauffmann read a paper on an interesting series of cases of Cerebral Degeneration in Children. He pointed out the relationship between diseases such as Friedreich's ataxia, cerebellar ataxia, and Little's disease.

SOCIETY OF ANÆSTHETISTS.—A clinical meeting of this society was held on Feb. 5th, Mr. C. Carter Braine, the President, being in the chair.—The President read notes of a case of so-called Waterlogging of the Lung ending fatally. He said that the condition was barely mentioned in text-books on anæsthetics and was generally due to the injudicious administration of ether when there were obvious signs that a mixture or chloroform should be substituted. The causes were (1) inhalation of fluid vomit; (2) inability to get rid of bronchial secretion; and (3) a combination of these two causes. Washing out the stomach was not a trustworthy remedy for the first cause as regurgitation still continued. "Waterlogging" of the lung occurred in feeble people of advanced age who had bronchitis and emphysema and was slow in its onset; the term should be confined to those cases in which there was inability to get rid of bronchial secretion. The case reported was that of a very fat old lady of the type just mentioned who had suffered from intestinal obstruction for three days. She was dusky in colour and had lately been drinking champagne. Owing to the danger from vomiting chloroform was administered and the operation performed while the patient lay in the lateral posture. Free vomiting and oozing of liquid occurred during the first 30 minutes but gave rise to no anxiety. The reflexes were never abolished. Then the helix of the ear became very blue, the pulse feeble, the respiration wheezy, cyanosis increased, and the patient gradually died. The chest appeared "waterlogged," as no air could be driven in or out of the lungs by artificial respiration. There was no post mortem examination but the President's opinion was that death was due to the choking of the tubes by gradual accumulation of bronchitic secretions and not to inhaled vomit, which always escaped freely.—The Junior Secretary read for Dr. T D. Luke of Edinburgh notes of a case of Great Danger during the Administration of Nitrous Oxide for the Extraction of a Single Tooth. The patient, a big, powerful man, became cyanosed, then vomited, and suddenly stopped breathing, becoming almost black. Tongue traction and artificial respiration were fortunately followed by recovery which was accompanied by great excitement. The patient, it was afterwards found, had recently had a meal, had been drinking port wine, had taken three quarters of a grain of morphine at night for ten days, and the day previously had been "sniffing" chloroform. Altogether he was an eccentric character. The reason of the vomiting was not obvious. Would the patient have taken ethyl chloride better?—Dr. W J. McCardie recorded a Death under Nitrous Oxide given for extraction of teeth in a man suffering from marked enlargement of the glands on both sides of the neck. The patient did not suffer from dyspnœa. After the administration of a small quantity of gas mixed with some air he stopped breathing and at once died without any apparent cause Post mortem both sides of the neck were full of enlarged and malignant glands, apparently secondary to malignant disease of the thyroid gland. The trachea was rather narrowed but not enough to cause an obstruction to breathing. No special cause of respiratory or heart failure was found.

KIDDERMINSTER MEDICAL SOCIETY.—A meeting of this society was held on Feb. 5th, Mr. E. S. Robinson being in the chair.—Mr J. Lionel Stretton showed the following specimens: 1. A large mass of Epithelioma growing from the Conjunctiva, firmly adherent to the globe of the eye, removed from an old man, aged 78 years. 2. A portion of the Skull removed by a Trephine from a boy, aged 14 years, containing a central hole which was part of a sinus leading down to the hypertrophied dura mater. He had suffered from middle-ear disease as a result of scarlet fever three years previously. The sinus was situated at a point one and a half inches behind a line drawn vertically through the external auditory meatus and one and a half inches above a line drawn horizontally through it. There was no history of an [illegible] for the condition. [illegible] to be that a subdu[illegible] bone, which must be an unusual occurrence. There had been no discharge since the operation and the wound was granulating up.—Mr. Stretton also read notes of cases of three females upon whom he had operated for Appendicitis within ten days. All made an uneventful recovery.—Mr. Stretton also showed a woman, aged 28 years, from whom he had removed a large Multilocular Ovarian Cyst. She was admitted to hospital with acute abdominal pain and vomiting and it was at first thought to be a case of twisted pedicle. No twist, however, was discovered. The cyst weighed 27 ounces and contained about three pints of fluid. In spite of a sharp attack of broncho-pneumonia she made a satisfactory recovery.—Mr. Stretton also showed a man, aged 83 years, upon whom he had operated for Enlarged Prostate. The gland, which was exhibited, weighed three and a half ounces and was removed by the suprapubic route.—Mr. Stretton also exhibited various Specimens.—Dr. B. Addenbrooke showed a case of Exophthalmic Goitre in a boy, aged 14 years, and an Ovarian Cyst which he had removed —Mr. W. Moore showed a specimen of a Horseshoe Kidney, the two kidneys being united and lying across the vertebral column.—Mr. Robinson showed a Fœtus with large Teratoma projecting from its mouth and being attached to the upper jaw.—Dr. O. C. P. Evans showed (1) a Brain with Abscess in the Right Temporo-sphenoidal Lobe resulting from middle-ear disease following scarlet fever; and (2) Sequestra removed from the Femur.—Dr. Evans also read notes of a case of Appendicitis in which abdominal obstruction, due to a band of lymph, came on after the operation, necessitating a further operation. The patient made a good recovery.—Dr. James Brocket showed a very good specimen of Fatty Heart removed from a woman, aged 65 years, who had committed suicide by cutting her throat.—Mr. Stretton read a paper on Professional Mistakes.—Many of the members present related their experiences.

Manchester Medical Society.—A meeting of this society was held on Feb. 3rd, Dr. Judson S. Bury, the President, being in the chair.—Mr. A. H. Burgess presented a communication on the Treatment of Rectal Prolapse and Incontinence of Fæces by the Submucous Injection of Paraffin, based on an experience of nine cases of prolapse, one case of prolapse combined with incontinence of fæces, and one case of incontinence resulting from operations for the cure of an extensive fistula in ano. He used a paraffin melting at 111° F. and a syringe the glass barrel of which was encased in rubber to retain the heat longer. No special means were taken to keep the needle hot. The technique of his operation was described in detail, the chief aim of which was to introduce the paraffin in successive tiers, each tier consisting of three large nodules placed equidistantly around the circumference of the bowel, the tiers being so arranged that a nodule of one tier was opposite to the interval between two nodules [illegible] of the tiers above and below it respectively. Usually three tiers were sufficient, but more might be introduced in a very long prolapse. A single stitch was placed to approximate the buttocks over the [illegible] to prevent the prolapse from descending before the paraffin had set, this stitch being removed in 24 hours. The results had been excellent in all the nine cases of prolapse, not a single instance of re-descent having occurred. In the case of prolapse with incontinence of seven years' duration a cure was effected by a combination of paraffin injections with a plastic operation to narrow the enlarged anal orifice. In the case of incontinence after operations for fistula the large amount of 52 cubic centimetres of paraffin was injected on two occasions submucously around the lower part of the rectum, and although the patient had previously been absolutely incontinent for three years he had not soiled his linen once during the eight weeks that had now elapsed since the operation.—Dr. Charles H. Melland gave some clinical details of a series of recurrent cases of Malaria recently met with in Manchester. After describing the principal points upon which a diagnosis of malaria should rest he dilated at greater length upon the value of blood examination in clinching the diagnosis. He then demonstrated, with Dr. Orr, a series of coloured lantern slides of microphotographs of Malarial Plasmodia taken from the cases referred to above illustrating the asexual life-history of the different species of plasmodia as studied in stained blood films —Dr. W. J. S Bythell gave a demonstration of the Sangers-Shepherd process of Colour Photography as applied to medicine.

Glasgow Obstetrical and Gynæcological Society —A meeting of this society was held on Feb 3rd, Dr. J. Nigel Stark, the President, being in the chair.—Dr. J. M. Munro Kerr showed: (1) A large Myomatous Uterus removed by supravaginal hysterectomy; and (2) an Ectopic Sac containing a Fœtus of about three months.—Dr. Samuel Sloan read a note on three cases of Cancer treated by the X Rays. The first was a case of Vaginal Cancer. Bleeding ceased and pain was diminished but the size of the growth was not influenced. The second was a case of Cancer of the Right Breast with destruction of the Breast Tissue and Involvement of the Axillary Glands. Under the influence of the x rays the ulcerated surface healed over but the malignant tissue in the breast and the axillary glands remained as before treatment. When treatment was stopped ulceration began again. The third was a case of Cancer of the Cæcum. Three applications were made and each was followed by great pain.—Dr. A Louise McIlroy read a paper on Some Pathological Conditions of the Fallopian Tubes, grouping illustrative cases into (1) hydrosalpinx, (2) hæmatosalpinx, and (3) tubal gestation As instances of hæmatosalpinx Dr. McIlroy showed two tubes from the same patient. There was no evidence of pregnancy in either of them. The uterus was myomatous. The hæmorrhagic condition was believed to be the result of pressure from the enlarged uterus. In illustration of tubal gestation the following cases were shown: (1) incomplete tubal abortion with hæmatocele; (2) incomplete tubal abortion where the non-pregnant tube of the opposite side was distended with blood; (3) a tube inclosing fœtus, where rupture had taken place into the broad ligament; and (4) a specimen of an unruptured tubal pregnancy.

Royal Medical Society of Edinburgh.—A meeting of this society was held on Jan. 29th, Dr. T. B. Hamilton being in the chair.—Dr. R J. A. Berry gave an address, illustrated by photographs, lantern slides, and diagrams, on the Anatomical Relationships of Two Double Monsters. In both cases the twins were united laterally, the union in the first case involving the abdomen and in the second both the abdomen and the thorax. The intestinal canals were found to unite in the duodenum and jejunum only and there was in each case a single liver. The heart in the second case was also a single structure but possessed four ventricles and two auricles. To one of the auricles three auricular appendages were attached, the other auricle having one. The auricles communicated by a well-marked foramen ovale and the interventricular septum on one side was absent. The primitive fault in this part of the monster was due to incomplete separation of the sinus venosus. From the various abnormalities observed Dr. Berry drew the important conclusions that the liver was not a fore gut but a mid gut development and that bilateral segmentation of a single ovum was unnecessary for the production of twins.—A Dissertation on the Relation of the Lower Animals to Disease in Man by Dr. J. A. Meikle was read in his absence by Mr. L. S Milne.—Dr. B. P. Watson read notes of a case of Ectopic Gestation which presented all the classical symptoms. On the morning of operation a decidual cast of the uterus was passed. Dr. Watson showed this cast together with the specimen removed at the operation. In this specimen the amniotic [illegible] cavity was visible in the centre of the mass of blood clot.

Otological Society of the United Kingdom.—A meeting of this society was held on Feb. 1st, Dr. Thomas Barr, the President, being in the chair.—The President delivered the introductory address in which he reviewed the work of last session. He remarked that a very large proportion of the communications had dealt with suppurative diseases of the ear and their complications and suggested that the society might devote a part of its time to a study of chronic non-suppurative diseases which did not endanger life but made it almost unbearable. It would be of great advantage to otologists to have authoritative guidance as to the comparative utility of the various methods of treatment in vogue.—Mr. C. H. Fagge exhibited specimens of Atresia Auris Congenita taken from a stillborn child showing bilateral absence of membrana tympani, ossicles, osseous meatus, and mastoid antrum.—Dr. William Milligan read a paper on the Etiology and Treatment of Suppuration of the Labyrinth which appears in full at p. 416 of our present issue. The discussion on the paper was adjourned to the next meeting.—Mr. Hunter F. Tod showed a specimen of Sarcoma of the External Meatus removed from a woman aged 67 years.—Mr. Hugh E. Jones showed a Portable Surgical Hand Motor.

Dermatological Society of Great Britain and Ireland —A meeting of this society was held on Jan. 27th, Dr. J. H. Stowers, the President, being in the chair.—The following cases were shown:—Dr. E G. Graham Little: A case of Scrofulodermia on the Buttocks of an Infant.—

Mr. T. J. P. Hartigan: A series of cases which were being treated by Radium—viz., three cases of Rodent Ulcer, four cases of Lupus, and one case of Facial Nævus.—Mr. Spencer Hurlbutt: A case of Lichen Planus.—Mr. George Pernet: A case of Lupus Erythematosus.—Dr. V. H. Rutherford: (1) A case of *Polymorphous Syphilodermata*; (2) a *case of* (?) Lichen Planus, (?) Syphilis; and (3) Perforating Ulcers of the Feet [illegible] xia with a history [illegible] (1) A case of Iodi [illegible] Preside [illegible] Universal Alopecia; and (3) a *case of Peliosis Rheumatica.*—D [illegible] of Hypertrophy of the Sebaceous Glands.

ABERDEEN UNIVERSITY MEDICAL SOCIETY.—A meeting of this society was held on Jan. 29th, Mr. James Clark being in the chair.—Mr. W. E. Reid read a short paper on Homœopathy. He instanced the use of aconite in milder febrile conditions as being the most outstanding example of drugs first used by homœopathists. Many drugs now in use were originally prescribed by them. Comparative statistics dealing with epidemics showed a lower rate of mortality for homœopathic treatment which was in widespread use in America and supported in this country by a good many of the medical profession. The paper was productive of much criticism.—Mr. R. H. Spittal followed with a paper on Occupational Diseases.

Reviews and Notices of Books.

A System of Physiologic Therapeutics. Edited by SOLOMAN SOLIS COHEN, A.M., M.D., Senior Assistant Professor of Clinical Medicine in Jefferson Medical College; Physician to Jefferson Medical College Hospital, to the Philadelphia Hospital, and to the Rush Hospital for Consumption. [illegible] Aerotherapy and [illegible] Dr. PAUL LOUIS [illegible] to Laennec and Lariboisière Hospitals, Chief of Clinic in the Faculty of Medicine of the University of Paris. Illustrated. London: Rebman, Limited. 1903. Pp. 479. Price 12*s.* 6*d.*

As many of our readers are aware this "System" is intended to present a "practical exposition of the methods, other than drug giving, useful for the prevention of disease and in the treatment of the sick." In its broad outlines the present volume follows the general plan of its predecessors but some important differences will be found in matters of detail. Considering the subjects which are now being dealt with we commend the editor and Dr. Tissier for this departure.

The history of the development of pneumotherapy and of its various methods receives a large amount of attention and supplies some instructive reading. Aerotherapy for many years suffered from the lack of persistent advocates and can hardly be said to have been appreciated at its true worth until the prominent position which has during the past few years been taken by the "open-air" treatment of tuberculosis aroused fresh interest in this branch of medical science.

The conclusions arrived at by the various observers who have investigated the physiological and pathogenic effects of condensed air and rarefied air, whether experienced by workers in caissons, by aeronauts in balloon ascents, or by mountain climbers, have not been entirely concordant. The therapeutical effects of artificially condensed and rarefied air have also given rise to markedly divergent opinions. Dr. Tissier sets forth the views of the various authorities in an able manner but the reader is not left in doubt amid a multitude of conflicting assertions and antagonistic recommendations as is so frequently the case when controversial matters are being dealt with. In many instances Dr. Tissier has succeeded in reconciling observations, apparently contradictory, by pointing out the diverse conditions under which they were made and suggesting the necessary corrections in the results.

Another particular in which the present volume differs from its companions is the attention given in Part II.—on Inhalation Methods—to certain aspects of pharmacology. This constitutes a departure from the strict title of the book but an advocacy of physiological therapeutics is not intended by the editor (Dr. Cohen) to disparage discriminating pharmacology; both are needed but the former has been too much neglected and deserves more recognition than has hitherto been given to it, hence the aim and origin of this series of treatises. The chapter on the Physiological and Pathological Effects of Compressed Air is an interesting one and the remarks on the therapeutic value of the pneumatic chamber are well worthy of notice. The use of compressed air has been found to be of considerable value in the relief of respiratory affections such as asthma and emphysema but it must be acknowledged that the treatment has not been largely adopted in this country, probably because there is only a very limited number of health resorts at which the requisite appliances are provided.

A full description is given of the various inhalation methods employed, more particularly in affections of the throat and nose.

This volume has an excellent index and the work will be found very serviceable for purposes of reference.

The Direction of Hair in Animals and Man. By WALTER KIDD, M.D., F.Z.S. London: A. and C. Black. 1904. 8vo, pp. viii-154.

THAT the direction of the hair slope in mammals varies much is a fact well known to zoologists; but we are not acquainted with any general work, such as the present, in which the facts are put together within one cover. The author has therefore in any case accomplished a piece of work which supplies a definite want in the literature of zoology. The usefulness of this general summary is furthermore enhanced by numerous clear figures which show at a glance the essential facts. The aim of Dr. Kidd is, however, more ambitious than that of merely summarising the arrangement of the various hair "currents" to be found among the mammalia, including man. He attempts, and often with considerable ingenuity, to interpret the variations in accordance with habit of life and he thus arrives, if we are to accept his readings of fact, at the important conclusion that acquired characters *are* inherited. Man offers an especially excellent example whereon to test such views. For we are better acquainted with the habits of existing man than with those of any other animal. We can thus test known concurrence of structure and habit in man with more doubtful concurrences in less known animals. This correlation may be illustrated by a few examples selected from Dr. Kidd's pages. He states, and shows in a diagram, that the hair slope in the dorsal region about the shoulder is upward in man, whereas it is downward in anthropoid apes. Now, as is justly pointed out, a very large proportion of the life of man is passed in slumber with the head more or less raised upon a pillow. This would plainly tend to produce an upward lie of the hair, since there is "a tendency of the body to slide downwards off the pillow." The author goes on to say that "in certain hairy subjects who have suffered a good deal from illness, necessitating much of the recumbent position, I have seen greatly exaggerated upward sloping of the hair on the dorsal region. I would submit that the mechanics required for the production of a very unexpected slope of hair are here ready to hand."

The lie of the hair on the head is clearly affected by the mode of parting the hair. The author has collected statistics to the extent of 100 persons and has discovered that "13 of these parted their hair on the right side, nine in the centre, and 78 on the left side." Now in the apes the hair upon the scalp has a uniform backward direction, though many of them, for instance, the bonnet monkey, have an obvious parting in the middle line. It follows therefore that if the trend of the hair were purely a matter of inheritance from apes, uninfluenced by later acquired and then inherited differentiations, the hair of the young would be more ape-like in its regularity than actual observations show it to be. While in numerous children the smooth and regular lie of the hair is to be found, others show distinct traces of formerly acquired partings; and we ourselves have seen perfectly reproduced in an infant a somewhat rare form of parting—more affected perhaps by a previous generation—namely, a parting at the back of the head. A considerable series of illustrations show the various forms of the hair tracts on the scalp in juveniles. As the author justly observes, it is likely that the primitive mode of the hair arrangement in mammals was a simple slope trending backwards from the direction in which the animal mostly moves, and he points out that this simple arrangement is to be found in a variety of mammals belonging to the more primitive orders. In the otter, for example, and in many marsupials the hair shows no complicated whorls such as are exhibited, for instance, in the dog and in the horse. Dr. Kidd's explanation would be, we suppose, that sufficient specialisation in habit and movement has not yet had time to influence the hair growth as it has in oxen, horses, and many carnivora. Yet to point out that in animals admittedly primitive the hair slopes are also primitive is somewhat of an imprudent revelation of truth. If the original character—i.e., a regularity of hair inset equal to that of scale and feather inset—has persisted so long without great change in one or more groups, why should the horse and the dog, which are modern types relatively speaking, have shown so markedly the influence of muscular actions and so forth? It would seem as if the oldest types were exactly those which should show the greatest amount of change. The only explanation from the author's, and indeed from the reviewer's, point of view seems to be the unsatisfactory one that this group and that have possibilities which a third has not. For example, the carnivora do not, and never have, developed aggressive horns upon the head, while the ungulata can and do. Hawks and owls are never bright green, while parrots and pigeons are so at times. The breeders know well enough that they cannot by any amount of artificial selection produce this modification or that in the objects of their attention. Putting aside such possible cases, it must be confessed that Dr. Kidd has made out a plausible argument in favour of the inheritance of acquired characters so far as concerns those features with which his book deals. But whether the reader is convinced by Dr. Kidd and agrees with our estimate or not, he cannot fail to be interested and instructed by a careful study of the volume before us.

LIBRARY TABLE.

How to Keep Well. By FLOYD M. CRANDALL, M.D. London: Grant Richards. 1904. Pp. 511. Price 6*s* —This work, the sub-title of which is "An Explanation of Modern Methods of Preventing Disease," is, we gather, written by an American physician for the instruction of the laity. As the author well says in his preface, "the time has come when the medical man should speak, not in his own defence, but in the defence of the people, who are easily misled to their own hurt." Altogether we have found it an admirable book. It does not teach people how to drug themselves but it sets forth the progress and functions of modern medicine in a plain manner, and Dr. Crandall writes with that mixture of shrewdness and geniality which seems to be the particular possession of our cousins on the other side of the Atlantic. One of the best chapters in the book is that on the Prevention of Breakdown and many a man if he follows the advice therein given will not only lengthen his life but will make it happier. Dr. Crandall quotes a saying of a well-known New York physician that he could do a year's work in eleven months but he could not do it in twelve, and then goes on to insist upon the need for all workers of an annual holiday. There is no doubt that he is right, for with the strain of modern life a holiday is not merely a pleasure but a necessity. Every man nowadays takes so much interest in health matters that we predict for Dr. Crandall's book a large *clientèle* of readers and if they only lay his dicta to heart they will be all the better for it, though Dr. Crandall's professional brethren will probably be the poorer.

A Manual for Students of Massage. By M. A. ELLISON. Second edition. Revised by GULIELMA MANLEY. London: Baillière, Tindall, and Cox. 1904. Pp. 126. Price 3*s.* 6*d.* net.—We reviewed the first edition of this unpretending little book in THE LANCET of Dec. 24th, 1898, and we see no reason to depart from the favourable opinion which we then expressed. The present edition has been brought up to date by the inclusion of some matter dealing with the use of massage in the treatment of recent fractures and sprains. The book lays down clearly what those who undertake massage should do and, what is equally valuable, what they should *not* do, *vide* the chapter entitled "Dont's," p. 95.

Herbert Fry's Royal Guide to the London Charities. Edited by JOHN LANE. London: Chatto and Windus. 1904. Pp. lvi.–391. Price 1*s.* 6*d.*—This very useful compilation is larger this year by some 150 pages than it was last year and, as we have mentioned before, it includes under the name of "Charities" a number of militant controversial associations which have no right to the name. These should be omitted, the more especially as we see that they are either unable or unwilling to give any "numbers of persons benefited." The book is so handy that we should like to see this blemish removed.

A Pocket-book of Clinical Methods. By CHARLES H MELLAND, M.D. Lond., M.R C.P. Lond. Bristol: John Wright and Co. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1903. Pp. 88. Price 1*s.* 6*d.* net.—This is a clearly written account of the various clinical methods for the examination of sputum, the gastric contents, fæces, urine, pus and other pathological fluids, and the blood. Little is said of the deductions to be drawn from the results of the examination since, in the words of the author's preface, "these points are fully dealt with in the text-books of medicine." The book is eminently practical and will be of great use both to practitioners and to students employed in the wards of hospitals.

The Purin Bodies of Foodstuffs and the Rôle of Uric Acid in Health and Disease. By I. WALKER HALL, M.D. Vict., Assistant Lecturer in Physiology at the Owens College, Manchester. Second edition, revised. Manchester and London: Sherratt and Hughes. 1903. Pp. 201. Price 4*s.* 6*d.*—This is a very important contribution on a very important subject and in the review of the first edition of the work, which was issued in pamphlet form, we briefly outlined the directions in which the author had conducted his interesting investigations. There is no doubt that the purins play an important rôle in the metabolic processes and therefore it is of importance that their amount should be known in the various foodstuffs. The author has designed an instrument, which he has called the "purinometer," for the estimation of purins in urine. In the present edition there is a new chapter dealing with the action of drugs upon the elimination of purin bodies, while the old title "The Significance of Food Purins in Metabolism" has been changed to "The Fate of Food Purins in Metabolism." In the appendix analytical details are given as is a table showing the constitution and calorific value of certain foodstuffs. The author has contributed some valuable work on points of the highest importance in dietetics.

A Laboratory Manual of Physiological Chemistry. By RALPH W. WEBSTER, M.D., Ph.D., Department of Physiological Chemistry, University of Chicago; and WALDEMAR KOCH, Ph.D., Department of Pharmacology, University of Chicago. Chicago: The University of Chicago Press; London: William Wesley and Sons. 1903. Pp. 107. Price 6*s*. 6*d*.—This book presents a straightforward laboratory course of physiological chemistry and so far as we have examined the experiments therein described, which refer to the chemistry of the cells, the preparation of the constituents in the tissues, and the chemistry of these tissues and of the digestive processes, they are clear and trustworthy in detail. The plan of the book is convenient and such as is likely to impart sound general knowledge of physiological processes. The work is summarised in an introductory note as follows: "The course begins with the study of the chemistry of protoplasm used in yeast as an example. The dependence of the reactions going on in yeast and other protoplasm upon the environment and the principles of chemical equilibrium are then taken up. This is followed by a study of the foods or raw products; their changes during cooking, digestion, and absorption; the chemistry of the blood and the master tissues, of the body, and finally the chemistry of the excretions." The subject is thus dealt with in a broad way having regard to its relationship not only to pathology, physics, chemistry, zoology, and botany, but to medicine and clinical chemistry. It is, perhaps, not a very important point but it is stated that milk should be neutral in reaction, whereas milk has when fresh an amphoteric reaction—the property, that is, of exhibiting apparently at the same time both a red and blue reaction with litmus paper. Generally speaking, however, milk may be said to be alkaline.

Hazell's Annual for 1904. London: Hazell, Watson, and Viney. Pp. 786. Price 3*s*. 6*d*. net.—This is the nineteenth year of issue of this most useful work which contains information upon most subjects which the would-be well-informed man wishes to know about. One remarkable feature about the book is that it is, to use the phraseology of the Liturgy, "indifferently" written—that is to say, even upon such burning questions as education and "passive resistance" it gives an impartial account of the matter under consideration. Altogether the work is a most valuable compilation.

The British Medical Association Year-Book for 1904. London: Published by the Association. Pp. 142. Price 1*s*.—This, so far as we know, is the first issue of a year-book by the British Medical Association and we think that it is a good departure. In it the reader will find everything that he wants to know about the Association, its officers, constitution, committees, and the like. A *résumé* of the last annual meeting at Swansea is given as well as information about the forthcoming meeting at Oxford.

Frondes Caducæ. By MONTAGU LOMAX. London: H. J. Glaisher. 1903 Pp. 112. Price 3*s*. 6*d*. net—This is a little book of poems which, as the author says in his modest preface, "are now published more in the hope of giving pleasure to the few who know me than to the many whose suffrages I am not competent to gain." Mr. Lomax has certainly a spark of the divine fire and his verses flow easily. The best, we think, is the song beginning "One day with many a loving vow I kissed my lady fair," which has quite a ring of Prior about it. We are glad to see that Mr. Lomax accents the name "Trafalgar" rightly, as will be seen from the sonnet on p. 111.

Victoria, Regina et Imperatrix, a Hymn Dramatic of Life and Death. By GEORGE B. BARRACLOUGH, M.A., M.R.C.S. Eng. London: Morrish and Co. 1903. Pp. 9. Price 1*s*.—We give Mr. Barraclough every credit for his loyalty but his verses are somewhat recondite, a difficulty he himself seems to have experienced. He says, for instance:—

"So faintly did he utter this
I hardly gathered its import."

We do not wonder, for what "he" said was this,

. . . .

. . . .

It is a God the twins occide,
And Dark the tomb where he abides
Within the chest his Body hides,
Till Hermes raise him for his bride."

Bettws-y Coed as a Health Resort. By a Member of the Medical Profession. Oswestry and Wrexham: Woodall, Minshall, Thomas, and Co. Pp. 41. Price 1*s*.—Bettws-y-Coed is such a charming place and is apparently still so old-fashioned that we are almost sorry that the "Member of the Medical Profession" has drawn attention to it. It seems to be an ideal place for a rest and the country round is full of objects of interest, especially for those who care for ecclesiology. How many are there, for instance, who know that Capel Curig is called after St. Cyriac who, together with his mother Julitta, was martyred in the Diocletian persecution? Bettws-y-Coed possesses a gravel soil, pure water, and pure air, together with an abundance of conifers, but we earnestly hope that it will never become fashionable and overgrown.

Lateral Curvature, Stooping, &c. By E. NOBLE SMITH, F R C.S Edin London: Smith, Elder, and Co. 1904. Pp. 133. Price 2*s*. 6*d*.—This little book gives a simple and practical account of lateral curvature of the spine which, as Mr. Noble Smith *rightly says*, may be called a *symptom* rather than a disease. The directions for treatment are sound and include the removal of the exciting causes, a discursus upon lying down, which is mainly mentioned as unsuitable, exercises, massage, and mechanical treatment. This latter chiefly resolves itself into the use of Chance's splint. The book contains an interesting chapter on the influence of diet upon physical development, while other chapters deal with the beneficial effects of development of the chest in cases of pulmonary tuberculosis. An excellent portion of the book is that dealing with clothing.

JOURNALS AND MAGAZINES.

The Monthly Review, which has now taken an assured place as one of the most important and responsible periodicals that we have, publishes in the February number some topical articles of great interest. Mr. Robert Machray discusses the crisis in the Far East with the simplicity that comes of knowledge of the subject; and his prophecy that "from a philosophical point of view the crisis is natural, inevitable, and is bound to come sooner or later, having its roots deep in history, its branches far outspread by forces always working in great, living, strenuous races," has already come true. Mr. R. A. Westenholz, president of the Agrarian League of Denmark, makes an important contribution to the fiscal question in an account of the present condition of Danish agriculture under free trade. Whether the conditions that have been so conducive to the agricultural prosperity of Denmark could have been enjoyed in this country during the past quarter of a century if our farmers had been more enterprising in the "sixties" and "seventies" and if our standards of technical education had received some little attention from politicians is another matter and one which is outside the scope of Mr. Westenholz's paper. A third article which calls for particular notice, written by Mr. Paul Waterhouse, deals with the facilities usually supplied for emptying theatres of their audiences. It is not altogether cheerful reading, for the general lesson conveyed is that the arrangements for escape from even the best London theatres in case of fire would be ineffective if the audience were panic-stricken, and it is almost impossible to conceive of any audience not being panic-stricken in the terrible circumstances of a conflagration within a crowded building. We agree with the writer that some measure of safety would lie in "an aggregate of preparation—a state of accumulated corporate pre-knowledge," but there is not much consolation in the reflection. This means that the audience would have to do fire-drill occasionally. how this is to be managed we cannot conceive. To let the audience know beforehand that they would have to undergo fire-drill is to remove the panic that alone precludes a well-built theatre from being evacuated in five minutes, while to spring a fire-drill upon the audience might be to risk killing as many people upon the false alarm as would have perished, presumably, in the case of a fire. In the site of the theatre lies the solution of the problem. We cannot return to the semicircular excavation of the hill-side wherefrom the Greek saw the drama despite the elements; but our authorities might recognise, in all future licensing of buildings, the enormous advantages of building a theatre on the side of a steep hill, and the necessity of abundant street frontage.

MEDICINE AND THE LAW.

The Jurisdiction of Magistrates in Cases of "Conscientious Objection."

AN evening newspaper which openly avows its hostility to vaccination recently published a paragraph headed "An Antivaccinator's Mecca" in which it stated that the magistrates at Heywood had in a single day granted "20 vaccination exemption certificates to applicants from all parts of the country," making a total of 53 such certificates during January, and further, that in the same place over 400 certificates of exemption from vaccination were granted during last year. Heywood, a manufacturing town and district in Lancashire, contains about 27,000 inhabitants and the birth-rate within the jurisdiction of the borough magistrates can hardly, according to previous returns, have exceeded 700 in 1903. If, therefore, the 400 children spoken of as exempted from vaccination last year were born, or were living, in Heywood we have a proportion of at least four unvaccinated children in seven in that locality on whose behalf the formality of obtaining an exemption certificate has been gone through and these figures take no account of those whose parents may have been able to ignore the law altogether with impunity. The paragraph, however, suggests that owing to the course taken by the Heywood magistrates persons not residing within their jurisdiction apply to them and receive exemption certificates for use elsewhere. We are not aware of the question whether this can legally be done having been before the High Court but Sir John Bridge in the early days of the Act had no doubt that it could not. A gentleman living at Wimbledon applied to him at Bow-street police-court on Sept. 1st, 1988, less than three weeks after the passing of the Act, and was told that his application could not be heard. The applicant relied on the fact that no mention of locality is made in the section which provides for conscientious objections. The legislature, however, no doubt intended that these should be considered and dealt with at courts within the district in which the unvaccinated child was, in fact, living at the date of the application. It certainly was not intended that special magistrates should be selected at will by parents on account of their known or supposed peculiarities. The paragraph in question may not accurately present the facts; if it does so it points to a very undesirable state of affairs. At the South-Western police-court Mr. Garrett on Feb. 8th gave a similar decision to that of Sir John Bridge.

A Point under the Public Health Act.

At Tottenham police-court on Jan. 28th Dr. J. F. Butler-Hogan, medical officer of health of Tottenham, applied for and obtained an order under Section 102 of the Public Health Act, 1875, to compel his admission to certain schools maintained at Tottenham by the Drapers' Company. The point for the magistrates' decision was whether the medical officer of health was entitled to an order for admission to any premises which he might think it expedient to visit and to which his admission was refused by the occupiers or whether before obtaining such an order he must show either that a nuisance requiring abatement existed on the premises or that he had reason to believe in its existence. The portion of the section upon which Dr. Butler-Hogan relied is as follows: "The local authority or any of their officers shall be admitted into any premises for the purpose of examining as to the existence of any nuisance thereon." If this sentence taken by itself supports the contention that the representative of the local authority may enter any premises for the purpose of ascertaining whether or not anything constituting a nuisance exists upon them, the rest of the section and those surrounding it are aimed at the abating of such nuisances as are known to exist and it cannot be said to be clear from them that magistrates may order private premises to be inspected at discretion. In the metropolis such an order cannot be made. This was decided in 1899 in the case of Vines *v.* the North London Collegiate School for Girls, referred to at Tottenham by the solicitor representing the Drapers' Company and reported in the *Justice of the Peace*, vol. lxiii., p. 244, a case involving facts similar to those which gave rise to the application at Tottenham but governed by a different Act of Parliament. The Public Health Act, London, 1891, the construction of which was there involved, contains words more clearly against the right to inspect at discretion than anything to be found in the general Act of 1875. As it is quite possible that the Drapers' Company may not be content to accept the decision of the Tottenham magistrates and as it may be able to have the matter reconsidered in the High Court further comment would be out of place. The matter is of interest, not in connexion with the particular schools in question, against which, as has been said, no cause of complaint is alleged, but because there are many institutions the sanitary arrangements of which are likely to be in a highly undesirable condition but with regard to which nothing may occur to call the attention of the local authority to any nuisance until an outbreak of illness takes place.

The Medical Man, the Coroner, and the Pathologist.

The *Star* in an article headed "The Wise Economies of the County Council," which appeared in its issue of Feb. 6th, attributed to THE LANCET an article which appeared in the *British Medical Journal*, commenting upon the employment of Dr. Freyberger to hold the necropsy upon Whitaker Wright. We do not wish to express dissent from the views of our contemporary as to the attitude of the coroner towards the medical profession, but merely to disclaim the credit of having expressed them on the occasion alluded to. *It would* not, however, be correct to say of us that "the regularity of the coroner's procedure is not called in question," nor do we agree with the *Star* that this describes the attitude of the *British Medical Journal* upon the subject. We have freely expressed the opinion that the employment of Dr. Freyberger by Mr. Troutbeck in many cases in which he has been employed has not been in accordance with the sections of the Coroners Act relating to the calling of medical witnesses at inquests. We have also suggested that if the employment of Dr. Freyberger is not in accordance with the law the fees paid to him by the County Council in respect of it are improperly paid and that the right way to raise the question is by calling the attention of the County Council's auditor to them If they have been wrongly paid it is his duty to surcharge them.

CAISSON DISEASE.—It is stated that five deaths have occurred in the execution of the foundation work for the Manhattan bridge, New York—three of them on the Brooklyn pier, which is now finished, and two on the New York pier, which is still in progress. The men are now working at a depth of 92 feet in two shifts a day of one and a half hours per shift with an interval of four and a half hours between shifts; the wages are 3½ dollars per day.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 13, 1904.

Public Affairs and Public Health.

A COMPLETE discussion of the actual or possible influences exerted upon public health by the course of public affairs would constitute a new and eminently interesting contribution to the etiology of disease. The happy condition of a nation that has no history, if such there be, must surround its constituent units, individually and collectively, with an atmosphere widely different from that to which we have become accustomed, and must render them exempt from many dangers to which we are prone. By the common consent of competent observers few things are more destructive of sound health than the class of demands upon vital force which are commonly described as "worry," and which arise, generally speaking, from uncertainty with regard to issues which are calculated to affect the prosperity of those whom they concern. The giants of the human race are able to cast off burdens of this description which fall with crushing weight upon the shoulders of weaker men. However they are engaged, whether in war, in politics, or in finance, they learn to decide quickly upon such elements of the problems presented to them as may be at the time available and, having decided, they act and wait. They dismiss the subject from their minds until the consequences of their action become apparent and until there is something more to be done. They harden their hearts against temptations to look back, or to reconsider that which is irrevocable, and devote their energies wholly to preparing for the future and to grasping it when it arrives. In this way, and probably in this way only, can the forces of the brain be entirely utilised and utilised in such a manner that no waste of power shall be permitted. The man who hunts yesterday's hare over again, or who dwells upon yesterday's letter, or who, by what our neighbours felicitously call *esprit d'escalier*, suffers his thoughts to linger upon the more effective manner in which it might have been possible to terminate last week's interview is giving his substance in exchange for that which is nought. He is squandering his nerve cells in a fashion which can yield him no return and which, not only by so much diminishes his power of using them fruitfully in other directions, but also, in all probability, converts some portion of the waste into material of a more or less toxic character. The first lesson of scientific education should be that a man's brain cells are not only money, but capital and that it is just as possible to dissipate them foolishly as to use them in the work of building up a career.

Great public events, of whatever nature, are certain to entangle in their meshes innumerable people who at first sight might be supposed to lie beyond their influence and who are absolutely without responsibility for their occurrence. Readers of "Vanity Fair" will remember old SEDLEY'S touching complaint of the consequences brought upon him by the return of NAPOLEON from Elba and by having trusted in the representations of the great Powers who had declared their intention of keeping him there. At this very moment the prosperity of England, or rather, perhaps, the prosperity of many Englishmen, may be brought into jeopardy by the circumstances which have kindled a war of which no one can foresee the termination, and which, even if we should escape from being dragged into it, will assuredly work many changes in our commercial relations, and dry up some at least of the channels through which they have been conducted. The wages of thousands of Lancashire operatives have been diminished by the proceedings of cotton gamblers in another continent and the interests of the employers of those operatives are themselves seriously endangered by the continuance of the same proceedings. The weather of the current year, so far as experience of it extends, seems to promise that the agricultural losses of the past are more likely to be exceeded than to be repaired; and, to crown all, the aggregate wealth of the nation is seriously diminished by the prices of securities. Such a combination of affairs cannot exist without bringing the potentiality of serious disaster to many, the certainty of ruin to some. It can hardly be doubted that the conditions must throw unwonted stress upon the lives of large numbers of our countrymen and countrywomen and must at least have some influence in predisposing them to suffer from disease. The hearts of many men must be "failing them for fear and for looking after those things which are coming on the earth," and by so much their resisting power must be diminished. They must walk warily if they would emerge victorious from a contest in which they cannot refuse to engage.

In such circumstances it surely behoves the members of the medical profession to justify their claim to be public advisers by giving such wholesome counsel as the occasion may require. Every man in practice comes into possession of knowledge concerning the affairs of his patients and is able, at the very least, to form shrewd guesses as to the various skeletons which their cupboards may conceal. It should be an important part of his functions to see that these skeletons are neither brought out for examination with undue frequency, nor ignored at times when a recollection of them might prove a safeguard against danger. If we think only of the future of England we may feel a conviction amounting to certainty that she will emerge from her trials, whatever they may be, stronger and more glorious than even in the past. We cannot conceal from ourselves the probability that the public events by which we are confronted will tell hardly, it may be even destructively, upon individuals, and our business is with individuals and with their preparedness for anything which the fates may have in store for them. We should instruct the harassed man as to the methods by which he may either husband his strength or waste it and should try to make known the value of prudence, of temperance, and of moderation. Among the temptations of such a time excess in the use of tobacco is not the least, nor is it the least certain to be followed at critical periods by comparative loss of the power to think with clearness and to decide with wisdom. Every practitioner must have seen examples of brain failure under conditions of anxiety and stress which have been more attributable to frequent "nips" of alcohol and to multitudinous cigarettes than to any real disproportion between the powers of the unpoisoned nerve structure and the work which it was called upon to accomplish. For every man whose commercial future is brought into danger by public events the wisest counsel is that he should keep in sound physical training. The more excellent the condition of his bodily health and the more wholesome his habits of life the more certain will he be, other things being equal, to master adverse circumstances by which a feeble man would be overcome. The pressure of anxiety does not necessarily mean disease, but it does mean an increased liability to succumb to its invasion. The part of the prudent is to be wise in time and to neglect no preparation for a contest of which it may be impossible to foresee either the duration or the severity.

The Spread of Small-pox by Tramps.

WHAT a potent factor in maintaining the prevalence of small-pox is that unemployed and largely unemployable degenerate the habitual vagrant or tramp who forms a prominent feature on the highways of our midland counties! The fact that this parasite upon the charity and good nature of the community is in his turn a vehicle for the spread of other parasites, both animal and vegetable, is common knowledge but practically no compulsory steps have been taken to curtail seriously the vagrant's movements or to promote his elementary cleanliness. Dr. P. BOOBBYER, medical officer of health for Nottingham, furnishes in a recent official report some admirable illustrations of the success which attends the efforts of the tramp to assist the conscientious objector in keeping small-pox from leaving our shores. The facts communicated in the report are remarkable. Dr. BOOBBYER tells us that at the beginning of 1903 a casual labourer, who at times figured as a professional tramp, was the means of spreading small-pox to no fewer than a dozen persons, the success of his efforts being apparrently due to the fact that he paid a visit to a public-house at a time when the trade was brisk. Shortly after this incident a tramp who had manifested a small-pox eruption for the past three days was admitted into the Nottingham workhouse and it appeared that in his recent wanderings he had passed through Loughborough, Leicester, Mansfield, and Doncaster. Again, but still in January, 1903, another tramp developed small-pox on arrival at H.M. Prison at Nottingham and two days later another of these unfortunate wayfarers presented himself at the Basford workhouse, Nottingham, with the eruption of small-pox just appearing. Yet another two days and a second brace of tramps suffering from the same disease were admitted into the same institution. Early in February a tramp suffering from small-pox was found in one of the common lodging houses *en route* through the town from north to south, and on the 15th of the same month a man who had tramped from Burton-on-Trent and who had manifested a small-pox eruption during the greater part of the journey was admitted into the Nottingham workhouse Another instance of infection by tramps occurred in February and in April a tramp from Loughborough and another from Mansfield were admitted into the Basford workhouse with a variolous eruption already well developed. During November three cases of small-pox occurred at Bulwell, a northern suburb of Nottingham, and others at Narrow Marsh, near the centre of the town, which had been infected by a tramp who passed through these two districts at the end of October (without detention) and who was ultimately discovered at Rothwell in Northamptonshire scarred by recent small-pox. One of this last series was instrumental in conveying the disease into the Nottingham workhouse where several persons were subsequently infected. Finally, by way of a crowning instance, Dr. BOOBBYER tells the story of a tramp who with the vesicular eruption of small-pox upon him paid a visit to a barber's shop and a public-house and was thus the means of infecting "at least 14 persons resident in various parts of the central and eastern divisions of Nottingham, including at least two in the Narrow Marsh district—one of the worst slums in the midland counties—from which neighbourhood a dropping fire of cases have been coming at short intervals ever since." This, then, is the unfortunate history of Nottingham.

But in illustration of the fact that the experience of this midland borough is in no sense exceptional we may refer to a report made by the medical officer of health of Newcastle upon "small-pox and vagrants in England and Wales" during the epidemic of 1891–93. In this paper Dr. HENRY E. ARMSTRONG stated that "of 63 urban districts invaded by small-pox in no less than 59 per cent. the disease was known to have been first introduced there by vagrants, and in 73 per cent. it was carried there sooner or later by this class. During the epidemic *secondary* introductions of small-pox by vagrants occurred ten times in each of 14 districts, 12 times in one district, 15 times in another, 18 times in another, and no less than 25 times in another." The report from which we have just quoted was instrumental in bringing together a conference under the auspices of the London County Council at which certain elementary recommendations were formulated and forwarded to the Local Government Board. They have not, however, yet got so far as the floor of the House of Commons. It is somewhat remarkable that the steps necessary to limit the mischief caused by these unfortunate vagrants have never been taken, not even so far as to require the vaccination and revaccination of persons in common lodging houses or casual wards who are exposed to the infection of small-pox. For ourselves we should like to see this subject taken up by some leading Member of Parliament, such as Sir MICHAEL FOSTER. We can hardly believe that if the facts which we have recorded were placed before the House with the eloquence of which the member for the University of London is capable the common-sense of the members would not carry the Revaccination Bill with an overwhelming majority. If the provisions of the much needed Bill, which we noticed in a leading article in our issue of Feb. 6th, p. 377, were properly carried out in the country generally, and applied with vigour in the vagrant wards, the charts of small-pox in England would henceforth be innocent of those black vertical lines indicating epidemic outbreaks of the disease. Will not Mr. LONG take under his powerful wing the Revaccination Bill and let his name be handed down to posterity as the Minister of Preventive Medicine who banished small-pox from the land?

Brandy *v.* British Brandy.

AT Church, near Accrington, five hotel-keepers have recently been summoned and fined 40*s.* each under the Sale of Food and Drugs Act, 1875, for selling as "brandy" to the prejudice of the purchaser an article not of the nature, substance, and quality demanded by him. Apparently the police entered each of the hotels in question and asked for a pint of brandy, when they were supplied in all cases with a liquid which is perfectly well recognised under the term "British brandy" but which, in fact, is not brandy at all. Brandy, as its name implies, is necessarily a grape spirit. The word is a natural abbreviation of "brandy-wine," a term once frequently used, which in its turn was an Anglicised form of the Dutch "*brande wijn*," or burnt wine—that is, the product of the distillation of wine. The manufacture of true brandy was fully dealt with in THE LANCET of Nov. 29th, 1902, p. 1503, and attention has been called in these pages on other occasions to the nature of the spirit sold in many public-houses and refreshment bars when brandy is asked for. The magistrates at Accrington are to be congratulated on having refused to believe that a man asking for brandy intends to receive an ardent spirit distilled from grain or from materials other than the juice of the grape when the recognised term British brandy exists should the purchaser choose to make use of it. The mere fact that the term British brandy has been invented and applied to the home product shows that at some time or other in the development of the English language it was felt that the word brandy by itself had a limited meaning, implying peculiar qualities. Apparently the solicitor for the defence in the recent cases at Accrington referred to the recognition of British brandy in Acts of Parliament of the seventeenth century. It is perfectly true that the possible manufacture of a spirit imitating brandy was early recognised by the Excise but this was in peculiar circumstances which have long since passed away and the spirit when first known seems to have been exclusively a subject of import.

Some of the old statutes upon the subject are of interest. The STUARTS, constantly in need of money, found strong liquors a convenient source of revenue and in two Acts of 1660 (12 Car. II., cc. 23 and 24) spirits are subjected to taxation in the following terms: "For every gallon of strong water or aqua vitæ made and sold to be paid by the maker thereof, one penny." "For every gallon of spirits made of any kind of wine or cyder imported, two pence." "For every gallon of strong water perfectly made, imported from beyond the seas, four pence." Ten years later a third Act (22 Car. II., c. 4) was found necessary in order to clear up an ambiguity. The preamble of this Act of 1670 is as follows:—

> "Whereas by two Acts made in the 12th year of His Majesty's reign and confirmed by this present Parliament there was laid upon every gallon of spirits, made of any kind of wine or cyder imported, the rate and duty of fourpence—namely, by each of the said Acts twopence—and upon every gallon of strong water perfectly made, imported from beyond the seas, the rate and duty of eightpence; and whereas some doubts have been made and raised concerning a certain liquor imported from beyond the seas, called brandy, whether the same should pay the rate and duty laid by the said Acts upon spirits made of any kind of wine or cyder imported or the rate and duty thereby laid upon strong water perfectly made imported from beyond the seas."

It is then declared "that the said liquor called brandy was at the time of making and confirming of the said Acts and is a strong water perfectly made and being imported from beyond the seas was and is chargeable in and by the said Acts with the rate and duty of eight pence per gallon." The deductions to be drawn from the passages which we have cited would seem to be that brandy was known in England not only in 1670 but even earlier, and that when the Act of 1660 was passed the "strong water or aqua vitæ" made in the country was not considered to be a form of brandy or a substitute for it, because if brandy had been recognised as similar to the already existing aqua vitæ it would have been taxed without question as a strong water imported. The Act of 1670, however, by its recital, shows that brandy was then a comparatively recent and not well-known beverage, that its preparation from the juice of the grape was recognised, and that it was regarded as a purely foreign spirit, taxable as such Twenty years later, however, there was a change, due to conditions arising out of war with France, and an Act (2 W. & M., c. 19) commences thus:—

> "Whereas by an Act made in Parliament held in the first year of their Majesties' reign, intituled 'An Act for prohibiting all trade and commerce with France,' all brandies, aqua vitæ, and spirits are prohibited to be imported into this kingdom, and whereas good and wholesome brandies, aqua vitæ, and spirits may be drawn and made from malted corn: For the encouragement therefore of the making of brandies, strong waters, and spirits from malted corn and for the greater consumption of corn and the advantage of tillage in this kingdom be it enacted ......"

At present happily we are far from being at war with France and there is no public demand for a so-called brandy made from potatoes, beetroot molasses, and other sources of alcohol which the ingenuity of chemists has discovered. We associate brandy, whether it comes from France, or Australia, or California, or elsewhere, with the distillation of fermented grape juice and nothing else. It was this distillation from wine which gave to brandy its high reputation centuries before the STUARTS reigned and before the imported beverage, no doubt highly popular with good livers under KING CHARLES II., became the gauger's prey.

The distillation of spirit from wine, under whatever name the product first figured, seems to have been the achievement of continental chemists in the thirteenth century and RAYMOND LULLY of Majorca, disciple of the actual inventor, ARNAULD DE VILLENEUVE, believing it to be a discovery of supreme importance to mankind, wrote of it thus in enthusiastic terms: "Limpid and well-flavoured red or white wine is to be digested 20 days in a close vessel by the heat of fermenting horsedung and then to be distilled in a sandbath with a very gentle fire. The true water of life will come over in precious drops, which being rectified by three or four successive distillations will afford the wonderful quintessence of wine." Processes may have changed in detail but when we ask for brandy, the term of Low German origin most generally employed in this country, we use a word implying (to those who seek its derivation) the "quintessence of wine," and we are glad to see that under so modern an enactment as the Sale of Food and Drugs Act we are entitled to get it.

In view of the importance of brandy from a medicinal point of view and the evidence of clinical experience it is satisfactory at length to find signs of some control being established over the sale of worthless substitutes. Good brandy is *par excellence* the medicinally valuable spirit and its timely administration has saved many lives. We are gratified to find that there is promise of the investigations of THE LANCET Analytical Commission upon this important subject bearing good fruit.

The Biological and Comparative Aspects of Cancer.

A CONNECTED narrative of the results of recent investigations into cancer by different groups of workers will lead to a better conception of the bearings of such work upon our present knowledge. The lines of inquiry which have led apparently to issues of importance have been essentially biological in character. It is no new thing to regard cancer from the biological standpoint, as all readers of THE LANCET know. We do not, however, here intend to refer to any prophetic expressions of early pathologists but only to consider essentially modern research. In an address on the Relation of Biology to Medicine delivered by Dr. Dr. J. ROSE BRADFORD and published in our columns on June 21st, 1902, p. 1747, it was distinctly pointed out that "whatever the nature of cancer may be a great amount of light will be thrown on that question by the researches of the pure biologist rather than by those of the human pathologist," and he indicated that this line of inquiry must of necessity throw light alike on the appearance which had been regarded as evidence of the presence of causative parasites and on the minute histology proper of the cell, which, in its relationship to cancer, had hardly been touched. It was not, however, until the Cancer Research Fund entered on its investigations that the biological and comparative aspects of the problem of cancer were approached in a serious fashion. And already this line of investigation has been productive of new facts, while, by placing upon a comparative basis all that has hitherto been recognised as essentially characteristic of cancer in man, it has given a new significance to long-recognised conditions. The extent to which cancer permeates the different divisions of the animal kingdom has not yet been fully ascertained, but the knowledge of the extent of its ramifications has been sufficient to narrow the field of inquiry to the few conditions which are common to the animal forms in which cancer occurs. Thus by an apparent extension of the field of inquiry in the first instance an actual narrowing of the investigation has been effected, and the facts ascertained by the comparative study of the zoological distribution of cancer will have to be reckoned with in future work on the malignant new growths from which human beings, in common with the lower animals, suffer.

The papers which have recently appeared have, we think, received somewhat precipitate publication, and the purely cytological observations placed on record have therefore not been brought into proper correlation; indeed, it is not improbable that much investigation will be necessary before this is attained. It often happens, when scientific investigation and thought are focussed on a problem at a time when it is ripe for study, that many independent workers approach the same goal by different paths. This has been the case with cancer, for while we have specially in our mind, as we write, three communications which have just been made public, it is well known that other observers than the authors of these papers have been drawn towards a similar solution of the problem of the nature of cancer. In the first of the three papers to which we are alluding, Professor J. B. FARMER, Mr. J. E. S. MOORE, and Mr. C. E. WALKER were concerned with the study of the cytological characteristics of malignant new growths in man. The occurrence in cancer of those types of cell division which had hitherto been regarded as peculiar to the reproductive tissues was placed on record and interpreted by the writers to signify that malignant new growths were virtually reproductive tissue. This conclusion was strengthened by an analogy drawn from plant life. The prothallus of the fern consists of cells which have undergone the peculiar reducing division in question, and it was stated that this reproductive tissue behaved towards the parent fern plant in the same way that a cancer behaves towards the human patient. It was further argued that the tissues of the asexual generation of the fern plant could be experimentally converted into reproductive tissue by external agencies and conditions. This fact was held to be analogous to the greater prevalence of cancer in certain districts or even houses. The publication, with the authority of the executive committee of the Cancer Research Fund, of the second paper was necessitated by the appearance of the first This paper, which was communicated to the Royal Society by Dr. E. F. BASHFORD, Director of the Cancer Research Laboratory, and Dr. J. A. MURRAY, has been already referred to by us in a leading article, and is published in full on p. 413 of this issue of THE LANCET. It seems to have already caused Professor FARMER, in an article which he has contributed to *Nature*, to modify the views originally held. Dr. BASHFORD and Dr. MURRAY set out the facts showing the extent to which cancer is found throughout the animal kingdom and the deductions based on the uniform character of malignant new growths notwithstanding their wide distribution. From these observations the conclusion is drawn by them that cancer must not be regarded from the standpoint of human pathology, but its cause and nature must be sought for in the potentialities which reside in the cells constituting the living body in divergent forms of animal life. In accordance with this view external conditions can only play a very subsidiary rôle, if any, in causing cancer. The conclusions are extended by giving comparative significance to the observations by Professor FARMER, Mr. MOORE, and Mr. WALKER on the nature of some of the cell divisions which occur in the malignant new growths of man. The occurrence of these peculiar mitoses is, however, regarded merely as a phase in the life-history of malignant new growths, which are not built up solely of cells comparable to the tissue of the fern prothallus or to certain cells in normal reproductive tissue. Dr. BASHFORD and Dr. MURRAY abstain from ascribing to the cells simulating reproductive elements either the absolute diagnostic value or the responsibility for malignancy which has been claimed for them and their descendants. It will be seen that they do not follow Professor FARMER and his colleagues, even while from a different standpoint they record confirmatory work.

Referring further to the paper which we publish this week, the potentialities residing in the cancer cells can be seen to be exemplified by observations on the transmissibility of cancer from one animal to another. It is demonstrated that in successful transmission the tumours which arise are the genealogical descendants of the cells actually introduced. The artificial transplantation of a malignant tumour is not regarded as throwing any light upon the origin of cancer, but as demonstrating that the proliferative activity of its cells can persist for a long time. This great power of proliferative activity, it is indicated, may depend upon the peculiar forms of cell division which some of the cells undergo. In other words, the cells which have undergone the peculiar reducing division may have prepared themselves for conjugation.[1] Conjugation is an act of fertilisation and when properly consummated gives rise to fresh generations throughout the entire animal and vegetable kingdoms. It is therefore not impossible that future work will show that many of those characteristics which are summed up in the word malignancy—the independence, the power of proliferation, the formation of metastases, and successful transplantation of cancer—are intimately related to the occurrence of cell conjugation. When it is stated that a malignant new growth belongs to a new cycle, comparable in its entirety to the organism which it is invading, it is not thereby implied that a malignant new growth is comparable to an embryo but rather that the cancerous tissue possesses the characteristics of a protozoan colony. Such, a little roughly speaking, are the lessons to be drawn so far from the consideration of the biological aspects of cancer. Enough has been established to make it of prime importance that systematic work on the same lines should go forward.

Annotations.

"Ne quid nimis."

MR. WALTER LONG AND THE LONDON COUNTY COUNCIL.

EFFORTS to save and to prolong life, to prevent disease, and to promote happiness are not, as a rule, attended by that glamour which waits upon those whose work is more particularly associated with the destruction of life and property and with the existence of disease and misery. Without entering into a discussion as to the ethics of this difference it affords us much pleasure to be able to record that the efforts of those who spend their lives in the war against disease have been recently acknowledged in a gracious fashion by the commander-in chief of the public health service of this country. It is now a considerable time since the public has been startled by announcements in the lay press that cases of exotic disease have passed our first line of defence and have gained a footing in the metropolis But it will not be without interest to the medical profession and to the public to learn that as recently as Christmas Day the officers of the Medical Department of the Local Government Board and of the London County Council were busily engaged in investigating a group of suspicious cases of illness which was by some regarded as being of the nature of plague. It will also be a source of satisfaction to the public to learn that so admirably were our defensive measures found to be organised that although in this instance the alarm was a false one the President of the Local Government Board directed that the following letter of appreciation should be sent to Mr. Shirley F. Murphy, the distinguished medical officer of the London County Council:—

Local Government Board, Whitehall, S.W.,
Jan. 1st, 1904.

[illegible]
connex [illegible]
ing of [illegible]
to be v [illegible]
Dr. S [illegible]

We congratulate Mr. Shirley Murphy upon this incident and we, moreover, express our appreciation of this graceful act on the part of the President of the Local Government Board. In order that there may be thorough efficiency in the public health service it is necessary that all branches of it shall work in harmony, and a word of recognition from time to time from the head of the service is one of the very best means of promoting such harmony and efficiency.

THE TRAINING OF MIDWIFERY NURSES AT THE ROTUNDA HOSPITAL, DUBLIN, AND THE REGULATIONS OF THE CENTRAL MIDWIVES BOARD.

WE publish elsewhere a copy of the correspondence which has passed between the Master of the Rotunda Hospital, Mr. E. Hastings Tweedy, and the secretary of the Central Midwives Board. It would appear that under the present regulations of the Board, by which a woman "must have attended and watched the progress of not less than 20 labours and personally delivered the patient, and, further, must have nursed 20 lying-in women during the ten days following labour," the nurses trained at the Rotunda Hospital are precluded from qualifying for admission as candidates to the examinations of the Board. This is due to the fact that in this hospital the patients as a rule leave on the eighth day following their confinement and, further, that it is impossible for each of the nurses, although they spend six months in the hospital, personally to conduct 20 cases of labour. As Mr. Hastings Tweedy aptly points out, six months' residence in a lying-in hospital is regarded by many of the examining bodies as affording the ideal training for a medical student, and when this period of time is so spent the personal conduction of any specified number of labours is not insisted upon. Certainly the facts brought forward with regard to the teaching of the midwifery nurses in the Rotunda Hospital would tend to show that the training which they receive is of the highest character and we have no doubt but that it is so. The Rotunda Hospital has long been considered one of the best training schools for students in midwifery and in these circumstances the training which its nurses receive is certain to be most efficient. This, however, is not a consideration which can be taken into account. The present curriculum for the midwifery nurses does not comply with the regulations of the Board as approved by the Privy Council for a period of three years from August 12th, 1903, and in these circumstances the Central Midwives Board had no alternative but to reply to Mr. Tweedy that it was impossible for it to make any alteration in the regulations. It is most unfortunate that the matter was not brought to its notice before the rules were approved as it is quite obvious that the training of these nurses is such as well to qualify them for the State examination. It will, however, still be some little time before the first of these examinations is held and in the meantime we hope that some way out of the difficulty may be found. It would obviously be regrettable if any permanent disqualification of the Dublin nurses were to ensue.

---

[1] A paper entitled "Conjugation of Resting Nuclei in an Epithelioma of the Mouse" was communicated to the *Royal Society* on Feb. 4th by Dr. Bashford and Dr. Murray.

GLADIATORIAL SHOWS.

WE are not among those who can see nothing that is good in public exhibitions of athletic skill in which danger is not entirely absent or in which the element of personal antagonism also plays a part. It is easy to deride such a sight as that of a recent great wrestling match and to declare that with all our vaunted advances we preserve the debased tastes of Rome in its degenerate days. Moralists in this strain are one-sided persons and they are also likely to miss important points. To begin with, there is all the difference in the world between a combat such as that to which we have referred and the gladiatorial shows of ancient Rome. In these there was not merely the chance of danger but the certainty of it and the probability of death itself was the piquant sauce which chiefly affected the jaded palate of the Roman spectator. Moreover, the gladiators were not, as a rule, free agents in the matter. They could not choose with whom or with what they would fight or whether they would fight at all. To witness such a sight as that of a man battling for his very life with an infuriated wild beast may be exciting but it can have no elevating influence of any kind. A very different effect is produced when two highly trained athletes choose to enter the ring for a fair trial of strength and skill. There is something stirring in the mere aspect of a fine specimen of physical development and condition. That same quality of admiration by which the typical Englishman is moved at the view of a splendid racehorse is not a thing to be deplored or despised and it is the same emotion in a higher degree which is aroused by the spectacle of human physical attainment at its highest point. In the latter case, moreover, the sight appeals more directly as an example and may lead in the case of many a beholder to some exercise of those admirable qualities of restraint, of self-denial, and of good temper without which a successful athlete is scarcely to be developed. A cavil might be raised that what we have said applies equally to the abolished prize-fight. That is true only so far as the combatants are concerned, it is not true with regard to the nature of their contest. Nobody objects to the skill, the strength, and the courage of the prize-fighter; it is the brutality which necessarily accompanies a competitive exhibition of these qualities in boxing that justifies the prohibition of the prize-fight. Wrestling entails no such brutality and though to our minds a far less interesting sport to witness than good boxing is yet a worthy incentive to physical training on the part of those who seek proficiency in the art. We have suggested that athletic exhibitions by trained experts are to be approved of because of the fine physical example, an emulation of which they may stir within the breasts of young men who witness their performance. It is spectators of this kind with whom alone we sympathise. The young man's inclination for athletic exercise and all the advantages that proper physical exercise entails is stimulated by watching those of greater prowess than his own and such a young man is the proper element in an audience such as that at Olympia. We confess to no sympathy at all with those who watch a contest for the mere excitement of it. The fat man who has never attempted athletics, who is chiefly attracted to boxing matches by the big cigar behind which he watches them and the big bet by which he may gain from them—such men as he have no more fitting place in the audience than has a woman or a child. The last two are out of place, because one would not if she could and the other could not if he would emulate the athlete's qualities.

THE HOSPITAL ISOLATION OF SCARLET FEVER.

WE have received a copy of a report presented to the health committee of the borough of Portsmouth by Dr. A. Mearns Fraser, medical officer of health of the borough, on the subject of hospital isolation of scarlet fever. Dr Fraser commences by stating that certain criticisms had appeared in the local press as regards the admission of patients into the Milton Hospital and that the board of guardians had written to the Local Government Board complaining of neglect on the part of the sanitary authority He wished to show that much misunderstanding existed on the subject. His remarks are of considerable interest and we are glad to note that the report was unanimously adopted by the Portsmouth sanitary authority together with a vote of thanks to Dr. Fraser for presenting it. On several occasions of late years it had proved necessary to keep patients waiting a few days before admission to the hospital. The patients were suffering from scarlet fever, diphtheria, or typhoid fever. This fact was deemed sufficient to found a charge of neglect against the sanitary authority by those who, without understanding fully all the circumstances, were apparently of opinion that it was the duty of the sanitary authority to have at all times in readiness an isolation hospital large enough to admit all the cases of infectious disease that might occur in the town. Dr. Fraser points out that on every occasion when patients had to wait for admission the cause has been the large number of scarlet fever patients and the large proportion of beds in the hospital that it was found necessary to devote to that disease. He therefore quite logically concluded that the determining factor in estimating the size of the hospital must be the number of scarlet fever patients to be admitted. He further tells the health committee that if it is proposed to maintain a hospital large enough to admit all cases of scarlet fever a hospital twice the size of the existing one would be required. As this would entail great additional cost he asked the question: "Is the benefit to the borough that will result from the admission of every case of scarlet fever that desires hospital treatment worth an additional £3000 to £4000 per annum?" In order to obtain assistance in arriving at the solution of this problem he gives certain statistics which are well worthy of attention. He first asks, "Is scarlet fever a disease of such great importance—i.e., is it a cause of so great a mortality or illness—as to warrant a large proportion of the rates being spent upon it?" He arrives at his answer by analysing the death returns of the borough for the past ten years. He gives a table comparing the mortality from scarlet fever with that from other diseases and shows that so far from scarlet fever being one of the most fatal it is actually one of the least dangerous diseases, the death-rate being decidedly lower than that from whooping-cough, diphtheria, typhoid fever, or measles. Next he considers the question, "Is scarlet fever a disease of such a character that the chances of the patient's recovery are greatly enhanced by hospital treatment?" Again the answer is in the negative. During the past ten years 5859 cases of scarlet fever were notified in Portsmouth. Of these, 3259 were treated in the hospital and 2600 at their own homes. Of the hospital cases 97·46 per cent. recovered whilst of the others 96·58 per cent. recovered. In relation to these two questions it must be remembered that the mortality from scarlet fever varies greatly in different epidemics but by taking the returns for ten years Dr. Fraser has to a great extent avoided a possible error. The death rate from scarlet fever also appears to be much lower in Portsmouth than it is in London. He next asks the all-important question, "Does isolation in hospital prevent the spread of scarlet fever?" He admits that this is a very difficult point to settle. He gives as his own personal opinion that the value of hospitals for infectious disease in the prevention of scarlet fever has been greatly over-estimated and he advances arguments in favour of this view. He states his case clearly and lucidly and the points which he raises are worthy of careful consideration; he particularly insists that his remarks must be taken as applying only to scarlet fever. Before expressing any definite opinion on the matter we think it would be of value if the medical officers of health of other boroughs would bring forward their statistics as corroborating or otherwise Dr. Fraser's conclusions. The question of providing accommodation for cases of infectious diseases is of the utmost importance to the community in general. At the same time the borough councils are naturally desirous of lowering expense so far as is consistent with the most modern views of medical science.

"A SCHEME FOR THE COMPARISON OF CLIMATES."

UNDER this title Mr. W. F. Tyler has published in pamphlet form[1] a paper which is reprinted from the February number of the *Journal of Balneology and Climatology*. Mr. Tyler is not a medical man but has had excellent opportunities of studying the subject during a long residence in Shanghai and as a Fellow of the Royal Meteorological Society he is likely to be acquainted with current ideas on this confessedly vague and uncertain topic. He assumes in the first place that the factors in the formation of climate are chiefly temperature, soil, prevailing winds, aspect, rainfall, humidity, altitude, and sunshine. He further assumes that the word climate is generally used to indicate, in respect to a particular locality, the effect of local conditions generally on persons of varying temperaments. Obviously, therefore, the estimation of climate does not admit of anything approaching the precision with which the meteorological and topographical conditions just mentioned can be expressed. The foundation of Mr. Tyler's proposed scheme is the idea of equal differences of sensations of various kinds and he thinks that the idea of climate is mainly the joint effect produced by temperature and humidity on the sensations of the inhabitants of the particular locality. In 1902 an attempt was made to give concrete expression to these sensations, or differences of sensations, by observations made on themselves at Shanghai by 12 individuals of normal condition and regular habits on each day of the month of August in that year. The word "hyther" was coined to indicate the sensation which is caused by a warm climate and is supposed to be due to the combined effect of heat and humidity. The observers, each for himself, estimated daily at noon the degree of "hyther" on a scale of 0 to 10. On this scale 10 represented the very worst day that the observers remembered to have experienced in Shanghai—hot, damp, and enervating; while 0 represented an ideal summer's day—warm, of course, but bright, brisk, and bracing, when a person suitably attired felt no discomfort from temperature and humidity. These records when plotted as diagrams on squared paper could not be expected to give approximately coincident curves, but, nevertheless, there was an amount of agreement between several of them which led Mr. Tyler to the conclusion that the principle was sound. A number of such graphic curves are shown in the pamphlet and their relations to the instrumentally recorded meteorological phenomena are discussed. In records of sensations it is evident that a great deal will depend on the previous training and the general psychology of the observer.

FALLACIES ABOUT FISH FOOD.

IT is doubtful whether any given food in common use contains constituents which have a selective action, so to speak, or the property of ministering to one part of the body more than another. As a rule, when a food is assumed to have specific reparative properties—as, for example, a so-called brain or nerve food—the fact really is that such food is easily and quickly assimilated to the body's general advantage; in a word, in such a case repair quickly overtakes waste and a real purposeful nutrition and restoration are accomplished. The administration of such elements as phosphorus or iron in medicine is, of course, a different matter, but these elements are evenly distributed in the materials of a daily diet. It is often stated that fish is a food which ministers particularly to the needs of the brain because it contains phosphorus. As a matter of fact fish does not contain more phosphorus than do ordinary meat foods and it certainly does not contain it in the free state. The notion that fish contains phosphorus had no doubt its origin in the glowing or phosphorescence of fish in the dark. This phosphorescence is due not to phosphorus at all but to micro organisms. The belief therefore that fish is a brain food is just about as reasonable as the idea that because a soup is thick and gelatinous "it will stick to the ribs," or as sensible as the celebrated advice to Verdant Green to lay in a stock of Reading biscuits to assist his reading. Fish, of course, is excellent food, partly because of the nourishing nature of its constituents and partly because of its digestibility. But it is in no sense a specific for brain or nerve. It is stated by some that a fish diet has an aphrodisiac effect; if this be so it is probably due to its favourable action upon the processes of nutrition and not to phosphorus. In connexion with this reputed property of fish food Dr. I. Barney Yeo quotes a remarkable passage in Montesquieu's "Esprit des Lois" which is as follows: "The founders of the religious orders who desired to subject their unhappy victims to the impracticable law of chastity wholly missed their end in prescribing for them the habitual use of fish."

THE SANITARY INSTITUTE.

THE following officers will preside over meetings of the next congress of the Sanitary Institute to be held in Glasgow from July 25th to 30th. President of the Congress, The Right Hon. Lord Blythswood, LL.D., D.L., J.P. Section I., Sanitary Science and Preventive Medicine: President, Professor J. Glaister, M.D., D.P.H., F.C.S. F.R.S. Edin. Section II., Engineering and Architecture President, Professor H. Robinson, M. Inst. C.E. Section III., Physics, Chemistry, and Biology: President, Professor Clowes, D.Sc., F.I.C., F.C.S. At the conferences, of which there will be eight, the following will preside:—Municipal Representatives: Councillor W. F. Anderson. Industrial Hygiene: Councillor J. Steele. Medical Officers of Health: Sir Charles A. Cameron, C.B., M.D. Engineers and Surveyors to County and other Sanitary Authorities: William Weaver, M. Inst. C.E. Veterinary Inspectors: Professor James McCall, F.R.C.V.S. Sanitary Inspectors:

---

[1] John Bale, Sons, and Danielsson, Limited, Great Titchfield-street, Oxford-street, London, W., pp. 31.

Mr. T. F. Strutt. Women on Hygiene: Her Grace the Duchess of Montrose. Hygiene of School Life: Professor J. Edgar, M.A. The public lecture to the Congress will be delivered by Sir Richard Douglas Powell, Bart., K.C.V.O., M.D., who has chosen as his subject the Prevention of Consumption.

THE HEALTH OF THE PRIME MINISTER.

MR. BALFOUR has been suffering from a somewhat severe attack of influenza accompanied by bronchial catarrh. Mr. Venning, finding on Sunday, Feb. 7th, that the bronchial symptoms were not clearing up so fast as he could wish, suggested a consultation with Sir Douglas Powell who has met him each morning since. The catarrh has now cleared away and Mr. Balfour was able to leave his bed for some hours on Tuesday, Feb. 9th There is every hope that the Premier will be able to go away from London for a change of air at the end of the present week.

LOCAL ANÆSTHESIA PRODUCED BY THE INJECTION OF WATER.

IN recent years operations have been performed under anæsthesia produced by injecting weak solutions of cocaine into the skin and subcutaneous tissue (infiltration anæsthesia). Schleich, who developed this method, asserted that the injection of water produced temporary anæsthesia but was painful. In the *New York Medical Journal* of Jan. 23rd Dr. Samuel Gant states that he has found the injection of water a most satisfactory anæsthetic in operations on the rectum, a region notoriously sensitive. It occurred to him to try this method on noticing that solutions of cocaine were practically inert when distension failed in consequence of the escape of the fluid through an ulcer or sinus. He began experiments in September, 1901, and recently has so improved the technique that he uses the method to the exclusion of general and medicinal local anæsthesia in a large majority of his operations on the rectum, such as those for the radical cure of fissure, hæmorrhoids, fistula, and prolapsus ani, excision of perineal cysts, sacral dermoids, and lipomata of the buttocks, and removal of foreign bodies beneath the skin and mucosa. The method is very simple. Sterile water and a sterilised hypodermic syringe with a long fine sharp needle are alone required. The temperature of the water is unimportant but warm water is preferable, as it causes the least discomfort. Saline solution does not appear to have any advantages. A fold of skin at one end of the line of incision is caught between the thumb and forefinger and compressed for a few seconds, which diminishes and often prevents the momentary pain caused by the first injection. The needle is quickly introduced between the layers of the skin and a few drops of water are slowly injected. A small localised distension, not unlike a blister, should be produced with immediate anæsthesia of the skin at this point. The needle is then inserted further and further along the line of the incision to be made, and the water is gradually injected, taking care not to go entirely through the skin. When the syringe is emptied it is refilled and the needle is re-introduced within the anæsthetised area. The injections are repeated until the whole line of the incision is distended. The needle is then plunged through this distended line and subcutaneous injections are rapidly made until a firm whitish ridge about as wide and thick as the index finger is produced. The deep injections may cause temporary discomfort which is due to the rapid distension of the subcutaneous tissues. If the procedure has been properly carried out the skin and subcutaneous tissue can be now incised without pain in almost every case. To remove the clot in cases of thrombosed external hæmorrhoids the injection need be made only between the layers of overlying skin. In excising external hæmorrhoids both the skin and the tumour should be distended tightly. Internal hæmorrhoids can be anæsthetised within 30 seconds by injecting into the centre sufficient water to turn them white. They can then be painlessly removed by excision, ligature, or clamp and cautery. In operations for fissure and fistula, which require division of the sphincter, the skin and subcutaneous tissue are distended up to the anal margin and finally injections are made into the mucosa, submucosa, external, and, if necessary, internal sphincter, until sufficient pressure is exerted on the nerve endings to abolish sensibility. The injection should be made slowly; rapid distension of this sensitive region may produce considerable discomfort. Ischio-rectal abscess if small may be incised after injecting the overlying skin, but Dr. Gant does not advocate the method for deep abscesses in which extensive cutting may be necessary or for other deep operations. The method possesses the great advantages of simplicity and freedom from risk of toxic effects which may occur with even weak solutions of anæsthetic drugs.

THE CENTRAL MIDWIVES BOARD AND WORKHOUSE NURSING.

THE Local Government Board appears to have taken up a position decidedly open to criticism as regards the qualification of midwives in workhouses. Section E of the rules of the Central Midwives Board which were approved by the Privy Council in August last and a copy of which appears in our issue of August 22nd, 1903, p. 555, expounds an elaborate scheme for "regulating, supervising, and restricting within due limits the practice of midwives." With the details of this scheme in so far as it insists upon the necessity for care and cleanliness on the part of the midwife we have no fault to find but its beneficial effects are nullified to a great extent by the extraordinary provision which concludes the Section. In Article 21 it is laid down that "nothing in this Section (E) shall apply to certified midwives exercising their calling in hospitals, workhouses, or Poor-law infirmaries under the supervision of a duly appointed medical officer." If this paragraph means anything at all it means that a workhouse midwife may practically be as indifferent to hygienic principles as she pleases, for as anybody with experience of workhouses can testify the amount of restraint which the "duly appointed" but usually non-resident medical officer can exercise upon her is very small. If, further, the midwife has received her certificate under Section D 4 of the rules as "having been in *bonâ-fide* practice as a midwife for 12 months previous to July 31st, 1902," she will be able to add to such indifference some of those quaint observances which have in past years done so much to maintain the rate of infant mortality. "Do you think that to wipe a new-born baby's eyes with the corner of a coarse dirty sheet is the proper way for a midwife to work?" Thus asks a correspondent in a nursing journal in reference to a practice met with in a workhouse. We, at any rate, do not think so; on the contrary, it seems to us that if there is any place where sanitary precautions are urgently called for it is in the labour ward of a workhouse. Hither drift the victims of venereal disease and here, as nowhere else, are the sins of the fathers visited on the children between whom and maybe blindness or death stands the care of the attendant nurse. In the matter of pauperism we are no sentimentalists but the children of the poor are a national asset and even the Local Government Board might be expected to be interested in seeing that such children do not, through neglect or incompetence, become a charge upon, instead of a support to, the State. We refer thus particularly to the Local Government Board because it appears from letters which have passed between the Workhouse Infirmary Nursing Association and the Central

Midwives Board that the rule to which we take exception was inserted at the express instance of the Local Government Board. *As a consequence of this interference it was decided* at a meeting of the Central Midwives Board held on Dec. 17th to postpone for the present all applications from teachers in Poor-law institutions who sought recognition under Section C of the rules. Thus a new obstacle is raised to the improvement of the status of Poor-law nurses and fresh discouragement is given to those who have been so long and so earnestly struggling for reform in workhouse administration.

THE SWEETNESS OF WINE.

IT is not always correct to attribute the sweetness of a wine to sugar, it may be due to glycerine or to the formation as age is acquired of sweetly-tasting ethers. The presence of glycerine in wines is frequently overlooked and yet this sweet body is always present but in varying amount according to the activity of the yeast concerned in the production of the wine. Sometimes the proportion of glycerine is as much as one-fourteenth of the volume of the alcohol. We have examined old wines which possessed a peculiar sweet flavour yet which on analysis showed a proportion of sugar quite inconsistent with the degree of sweet taste. Such a wine would be rejected by many because the sweetness would be regarded as an indication of an undesirable proportion of sugar. The sweetness which sometimes develops in old wines may be due to the disappearance of the acids, their sour taste masking the natural sweetness of the wine, while as the acid flavour diminishes by the separation of the acids in the form of "crust" the palate more readily recognises the sweetness of the glycerine. Possibly also as age is acquired the glycerine combines with the acids, forming new compounds which are sweet to the taste. The ethers of wine dissolved in alcohol are perceptibly sweet to the taste. In the same way old matured spirits possess quite a sweet flavour which, according to analysis, is due neither to glycerine nor to sugar but to subtle ether compounds. A molecular rearrangement takes place by which certain constituents which in their original state were nauseous when the spirit was raw and young become palatable. Sweetness is a physical property which belongs to other substances besides sugar, just as many things share a similar odour. At one time, of course, the word sugar was inseparable from sweetness and there are persons even now who when they find that a substance is sweet have only the one idea that it is due to sugar. Sweetness is probably only a matter of chemical structure and given the atoms in a certain position in the architecture of the molecule sweetness becomes a property of the substance. This property is not only represented in sugar, glycerine, saccharine, and certain compound ethers, but in quite a large number of organic compounds synthetically built up by the chemist.

YELLOW FEVER.

IN THE LANCET of August 8th, 1903, p. 389, we published a review on Dr. Scheube's third edition of "Die Krankheiten der Warmen Lander," in which the following passage occurred: "We are glad to find that Dr. Carlos Finlay is mentioned as being the first to draw attention to the mosquito theory of yellow fever in 1881. This observer caused the mosquito to sting a yellow-fever patient and then to inoculate an individual previously free from the disease, with results showing infection in 22 out of 24 patients experimented on, the remaining two being lost sight of." We have since received a communication from Dr. Finlay in which he states that this proportion of successful inoculations has not been reached. He *forwards a pamphlet by Dr. T. V. Coronado, entitled* "Dr. Carlos J. Finlay and his Theory," in which it is shown that out of 104 non immunes whom Dr. Finlay and Dr. Delgado inoculated in the course of 20 years only 17 showed any *perceptible pathogenic reaction within the 25 days following* their inoculation. Dr. Finlay considers that "the only practical inference which can be drawn from these inoculations lies in the fact that such a large proportion of the inoculated subjects never suffered thereafter from any form of yellow fever during the subsequent years of their residence in Havana and that only five of the 104 died afterwards from yellow fever."

THE RESPONSIBILITY OF SUICIDES.

BENTHAM, writing in the earlier half of the nineteenth century complained that juries were constantly guilty of perjury when they declared a suicide to have been *non compos* at the time of his decease The recent verdict upon Whitaker Wright would have seemed to the great jurist to mark a return to ancient candour, however much the announcement that a man had a motive for suicide and died in his senses may startle people to-day. The verdict of the jury and the coroner's remarks at the inquest on the body of Whitaker Wright should, indeed, serve as a reminder that the law does not necessarily regard suicide as the result of insanity, and that even where it seems to admit insanity it isolates it in a manner quite contrary to scientific ideas of causation. In cases, for instance, where suicide has closely followed the making of a will, the law has repeatedly refused to invalidate the testament because the testator took his own life shortly after writing it The notion that a man is out of his senses when he commits suicide really dates from the day when the Church insisted that suicides, as persons guilty of self-murder, should be buried with the utmost ignominy. Lay jurymen in those days, to save their fellow creatures' bodies from disgrace, preferred to suppose that a suicide was insane at the time of death and therefore irresponsible. The plea of insanity in early times was frankly put forward as a legal fiction, actuated by kindness, and as such was probably freely accepted by individual priests. It is difficult to say exactly when what now seems to be a firmly rooted belief began to prevail that a suicide is out of his senses at the time when he puts an end to himself. In the eighteenth century a connexion between abnormal mental conditions and suicide appears gradually to have arisen, and in 1788 "self destruction" and "phrenzy" occur in the same book-title as though the one connoted the other. In 1804 Dr. William Rowley in his "Madness and Suicide," traced *felo de se* to lunacy and the latter often to merely physical irritations.

THE SYMPTOMS OF TUMOUR OF THE PITUITARY BODY.

THE subject of tumours of the pituitary body has lately received much attention in neurological medicine and it is now known not only that mental torpor and somnolence result from lesions of that organ but that characteristic nutritive changes in the osseous system allied to acromegaly and gigantism may be the outcome of disease of the pituitary body in youth or early adult life. In the *Revue Neurologique* of Dec. 30th, 1903, Dr. R Cestan and Dr. Halberstadt publish an account of a case of pituitary tumour which throws light on some obscure points in the pathology of this affection. The patient was a man, aged 60 years, who had suffered for some time from symptoms of epileptic vertigo, progessive enfeeblement of memory and of intelligence, headache, and marked somnolence interrupted by occasional attacks of agitation. He was regarded as a case of premature senile dementia and was placed in an asylum. He remained in a state of apathy and somnolence and eventually died after a series of attacks of *dyspnœa*.

There were no acromegalic or osteo-hypertrophic changes but there was marked adiposity. The necropsy showed the presence of a tumour of the pituitary body "of the size of a small nut," vascular, cystic in character, and practically limited to the sella Turcica. It showed a small prolongation passing upwards into the third ventricle. It was a cystic adenoma and in its histological character presented features identical with those occurring in a case of gigantism to which reference has been made in THE LANCET.[1] Attention is drawn by Dr. Oestan and Dr. Halberstadt to two points of interest in the present case—viz, first, the absence of skeletal changes and, secondly, the presence of mental changes, such as apathy, enfeeblement of memory and of intelligence, and somnolence. Such mental changes have been noted in cases of pituitary tumour by Woolcombe,[2] Fröhlich, and Schuster (1902). The last-mentioned writer states in a monograph on the subject of cerebral tumours accompanied by psychical disturbance that out of a total of 775 such cases 61 were due to tumour of the pituitary body. Somnolence as a marked feature has been noted by Soca (1898), Schuster, and others. To reconcile the view that osteogenetic changes (acromegaly and gigantism) may occur in some cases of pituitary tumour while absent in others Dr. Oestan and Dr. Halberstadt suggest that when pituitary tumours or lesions appear in infancy they affect the nutrition of the osseous tissues and produced gigantism, that when they occur in early adult life the result is acromegaly, and, finally, that when the affection supervenes in middle or old age, after the osseous and other tissues of the body have attained the maximum of growth, the result is a preponderance of the mental symptoms of apathy and somnolence combined with obesity, as in the case to which reference is made above.

POOR-LAW MEDICAL OFFICERS AND SUPERANNUATION.

A MATTER affecting the interests of medical men concerned in the administration of the lunacy law has just been dealt with by the Local Government Board and although we regret the decision come to we note incidentally that it bears out entirely the opinion expressed recently in these columns as to the position of workhouse medical officers in regard to fees for certifying pauper lunatics. On the superannuation of Mr. W. Buchanan, late medical officer to the Medway union workhouse, the guardians of that union resolved to grant him an allowance based upon the fees which he had received for the examination of lunatics during the past five years. The district auditor disallowed the payments and surcharged the guardians who authorised them with the amount. An appeal to the Local Government Board resulted in a confirmation of the auditor's decision, the following reasons being given for the attitude adopted. "It forms no part of the duty of a medical officer of a workhouse to make the examinations to which the auditor refers and it is open to the justices, whatever their practice may be, to call in any medical practitioner for the purpose. Consequently the medical officer of a workhouse seems to be in the same position as any other medical man and the fees paid to him under the Lunacy Act, 1890, by order of the justices are not paid to him in his capacity as medical officer of the workhouse. Hence the Board are of opinion that the fees in question cannot be regarded as emoluments of Dr. Buchanan's office and should not have been taken into consideration in calculating the amount of his superannuation allowance." In another part of the letter the same principle is enunciated in these words: "Although the guardians have passed a resolution that Dr. Buchanan should examine all lunatics, the power to call in a medical man rested with the justices and the resolution of the guardians was of no legal effect." It will clearly be advisable in future for workhouse medical officers on accepting appointments to have their position in regard to emoluments properly defined. In some cases the fees for certifying lunatics constitute quite a large proportion of the salary, so that the amount at stake may be considerable.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE following lectures for the present year will be delivered at the Royal College of Physicians of London, Pall Mall East, on the dates named below at 5 P.M. The Milroy lectures will be delivered by Dr. W. Williams on February 25th and March 1st and 3rd, the subject being Deaths in Childbed, a Preventable Mortality The Goulstonian lectures will be delivered by Dr. R. Hutchison on March 8th, 10th, and 15th, the subject being Some Disorders of the Blood and Blood-forming Organs in Early Life. The Lumleian lectures will be delivered by Dr. F. Taylor on March 17th, 22nd, and 24th, the subject being Some Disorders of the Spleen.

A CASE OF CHRONIC PANCREATITIS.

MOST recent writers on diseases of the pancreas have entered a plea for the more careful observation of the clinical phenomena of such cases and more regular and systematic examination of the pancreas at necropsies in order to furnish workable data for the filling up of the numerous gaps in our knowledge of the normal and pathological conditions of this important organ. Dr. Ferdinand Ehler of Brünn has carefully recorded a case of chronic indurative pancreatitis in the *Wiener Klinische Wochenschrift*, No. 51, 1903, which presents several features of interest from the clinical and pathological standpoint. The patient was a woman, aged 56 years, who with the exception of a few slight gastric attacks had enjoyed good health until five months before going to hospital, when she suffered from severe lumbar pain which, however, soon ceased so that she was able to return to her work. Four months later she had a recurrence of these pains, more severe in character, and radiating to the abdomen, rapidly followed by an intense jaundice. There was no history of syphilis or alcoholism. On admission to hospital she was described as a cachectic, emaciated woman of apathetic expression and olive-green complexion. The pulse was irregular, weak, and its rate was 60 per minute The abdomen was slightly distended but not rigid or tender and there was no ascites. A tumour of the size of a goose's egg was felt beneath the right costal margin, presenting the characters of a distended gall-bladder. The liver was moderately enlarged, its edge being felt below the costal margin. The spleen was normal in size. The bowels were opened once or twice daily, the motions being of thin consistence and free from bile pigment. The urine was dark, bile-stained, and free from albumin and sugar even after the administration of milk sugar. The temperature was subnormal, ranging between 36° and 36·5° C. The alternative diagnoses of gall-stones or of carcinoma involving the bile-ducts were made and laparotomy was performed, the distended gall-bladder being found and opened, but no gall-stones were discovered. On deep palpation towards the left side a hard tumour could be felt which was regarded as carcinoma of the pancreas. The patient died four days later from pneumonia and cardiac failure. At the necropsy no carcinoma was found but there was a condition of chronic indurative pancreatitis; there was a retention cyst of the size of the fist in the tail of the organ filled with turbid fluid of chocolate colour, the rest of the parenchyma being markedly indurated and permeated by fibrous bands. The common bile-duct was compressed and obstructed below and dilated above the obstruction. The liver was enlarged but showed no definite pathological change. The stomach was slightly dilated but its mucous membrane presented no macroscopic alterations. There were some fibrous myocarditis and a recent croupous pneumonia. Microscopically the pancreas showed marked overgrowth of fibrous tissue, apparently starting around the vessels and small ducts and thence invading the parenchyma of the organ. The interest in the case, considered pathologically, is that it was apparently primary and not the result of syphilis, alcoholism, or gall-stone obstruction, as these cases often are, and Dr. Ehler was inclined to regard this case as originating from a vascular change in the gland of the nature of arterio-sclerosis and referred in support of this to the fibrous condition of the myocardium (although no atheromatous changes were found in the aorta) and to the condition of the vessels of the pancreas, which were distinctly thickened. The interest from the clinical standpoint is that this case supports Courvoisier's dictum that jaundice in association with distended gall-bladder is usually due to obstruction of the common duct from some other cause than gall-stones.

[2] Brit. Med. Jour., June 23rd, 1894, p. 1351.

THE RESUSCITATION OF DR. A. DARIER.

THERE was once an American editor who received a cal from an indignant gentleman whose death he had chronicled in his paper. The indignant gentleman, producing himself as proof of his words, demanded that a statement should be made in the paper that the editor was at fault. To this the editor replied that in his paper no mistakes were ever made, adding that, if they were, they were never acknowledged. After some argument, during which the editorially deceased person was able to show that he had a real grievance, the situation was met by the editor who, repeating the impossibility of making a public declaration of error, added that he would publish his visitor's name in the next list of births. It has been brought to our attention that in a summary of the ophthalmological work of the year 1903 we referred to Dr. A. Darier, joint-editor of *La Clinique Ophthalmologique*, as deceased. This, we are very glad to say, was a mistake, and we admit it with none of the reluctance to say *peccavi* that was shown by our American colleague in the story. We resuscitate Dr. Darier in a conspicuous part of THE LANCET and not in the birth column. We regret not to have made this *amende* to him sooner, but no exact reference was given to the place in our columns where the slip had occurred, and until now we were unable to find that we had cut off the well known French ophthalmologist in his prime. We trust that he has not been seriously inconvenienced.

THE INTERNATIONAL CONGRESS FOR SCHOOL HYGIENE.

THE first international congress for school hygiene will be held at Nuremberg from April 4th to 9th and in connexion with the congress there will be an exhibition of objects referring to school hygiene. Much interest has been taken in the announcement of this exhibition and the committee therefore intends to open it some days before the commencement of the congress and to keep it open for some days after the congress has closed. All objects referring to school hygiene may be exhibited, such as plans and models of school houses, treatises on the principles of school-house building, treatises on the education of children both at school and at home, school furniture, books, drawing instruments, and apparatus for the medical examination of children and for their physical education, such as gymnastic appliances and the like. The exhibition should, we think, prove of great interest and as an example of what can be done with old-time material we suggest that "our Colleges of Westminster, Winchester, and Eton" be asked to send models of some of their older schoolrooms. Many of these are such as would cause a zealous School Board member to faint from horror and yet the institutions possessing them turn out boys who become men of great value to the State.

TUBERCULOSIS IN DAIRY COWS.

WE have received a copy of a pamphlet with the above title written by Dr. J. Wright Mason, medical officer of health of Hull, and Mr. James McPhail, M.R.C.V.S., chief meat inspector. The writers point out that municipal and local authorities have obtained stringent powers to deal with tuberculosis amongst dairy cows. They have therefore published this pamphlet to give information couched in simple terms to persons in charge of dairy cows and to those who are directly interested in such legislation. They have succeeded well in this laudable object and have described in language devoid as far as possible of technical terms the symptoms which may be observed in cows suffering either from acute or chronic tuberculosis. The dangers that are attendant on drinking milk from a tuberculous cow when the udder is affected are strongly insisted on. The symptoms of this affection are indicated and although the dairyman cannot be expected to make a diagnosis of tuberculosis, yet when he finds the parts in the condition described it is undoubtedly his duty to draw the attention of his employer or the veterinary surgeon to the diseased animal.

RUPTURE OF THE TENDON OF THE EXTENSOR LONGUS POLLICIS.

IN the *Boston Medical and Surgical Journal* of Dec. 10th, 1903, Dr. C. L. Scudder and Dr. W. E. Paul have described a very rare injury—rupture of the tendon of the extensor longus pollicis. A woman, aged 58 years, fell and struck the back of her left hand on the edge of a stone step. There was tenderness near the proximal end of the first metacarpal bone and in dressing herself the patient felt pain at that place. Three weeks later, when the hand felt practically well, on attempting to take hold of a chair she found that the left thumb could not be used and remained flexed in the palm. Examination on the next day showed that the proximal phalanx of the thumb could not be extended, so that in grasping movements the thumb was closed upon by the flexed fingers. Feeble extension of the distal phalanx was readily performed. All movements of the metacarpal bone were executed but the range of extension and abduction was diminished. The only indication of the site of the rupture was the patient's assertion that there was some tenderness on using the hand near the proximal end of the dorsum of the metacarpal bone. Rupture of the tendon of the extensor brevis pollicis near its insertion was thought probable. Six weeks later an operation was performed. The tendon of the extensor longus pollicis was found to be ruptured near the proximal end of the metacarpal bone. The sheath was intact. Careful dissection along the wrist was necessary in order to find the retracted muscular belly, which was six or seven centimetres from the distal end of the torn tendon. Approximation of the ends of the ruptured tendon was impracticable. Tendon transplantation was therefore performed. The tendon of the extensor carpi radialis longior was partially cut on its radial aspect and split along its length for about three centimetres. The distal fragment of the tendon of the extensor pollicis was cut transversely to secure a smooth surface. The tendons thus prepared were united by three fine silk sutures. Eight months later grasping movements could be performed with opposition of the thumb. The range of extension of the terminal phalanx was about one-third of normal and of the proximal phalanx about two-thirds but the patient was still improving. Dr. Scudder and Dr. Paul explain the injury as follows. The fall partially severed the tendon of the extensor longus pollicis. Three weeks later rupture was completed by muscular effort. The loss of movement does not agree with the usual description of the action of the extensors of the thumb. The long extensor (extensor secundi internodii pollicis) was evidently the extensor of the first phalanx. Extension of the second phalanx appears to have been performed by the short extensor (extensor primi internodii pollicis) and the abductor pollicis. A possible explanation is that the insertions of the extensor tendons were abnormal. We should like to know the evidence on which the operator identified the tendon as that of the extensor longus pollicis. May not the tendons of both extensors of the thumb have been injured? The operation performed in this case seems to us open to the objection that the function of the long extensor was not restored.

UNIVERSITY OF OXFORD: THE PHILIP WALKER STUDENTSHIP IN PATHOLOGY.

A STUDENTSHIP in pathology has just been founded in the University of Oxford by Mr. P. F. Walker for the furtherance of original research in pathology. The studentship is to be of the annual value of £200 and may be increased, if at any time the income of the endowment fund exceeds £200, to any sum not exceeding £300. Prizes or grants may also be made from the fund in similar circumstances to persons engaged in pathological research. The studentship is not confined to members of the University and is open without limitation of age or sex. It is to be awarded by the managers of the fund upon the report of the reader in pathology on the respective qualifications of the candidates and is tenable for three years from election, with a possible extension on the recommendation of the reader for a further period of two years. During his tenure of the studentship the student is prohibited from following any business or profession or engaging in any educational or other work which in the opinion of the managers of the fund would interfere with his original inquiries. The place and nature of the studies of the student are to be subject to the approval of the reader in pathology, provided that the student shall be bound to pursue his studies within the University during at least three terms of his tenure of the studentship, unless this requirement be dispensed with for special reasons. The full details of the Decree of Convocation and the regulations governing the studentship are published in the *Oxford University Gazette* of Feb. 2nd (University Press, 116, High-street, Oxford. Price 3*d.*).

THE medical officer of health of the Cape Colony states that for the week ending Jan. 16th two cases of plague were discovered in the Colony—namely, a coloured male found dead on Jan. 11th and a native male who died on Jan. 14th, both at Port Elizabeth. Dead rats were found at Port Elizabeth, East London, and Knysna, but of 304 rats examined in the Cape Town and Harbour Board area none was affected with plague. As regards the Mauritius a telegram from the acting governor received at the Colonial Office on Feb. 5th states that for the week ending Feb. 4th there were 17 cases of plague and 14 deaths from the disease.

THE anniversary dinner of the Medical Society of London will be held at the Whitehall Rooms of the Hôtel Métropole on Tuesday, March 8th, at 7.30 P.M. Communications should be made to the honorary secretaries, Dr. H. A. Caley and Mr. H. J. Waring, at the rooms of the society, 11, Chandos-street, Cavendish-square, W.

THEIR Majesties the King and Queen, accompanied by Princess Victoria, have announced their gracious intention to visit the University of Cambridge on Tuesday, March 1st, to open the new schools for medicine, law, and botany and the Sedgwick Museum where the King will unveil a statue of Professor Sedgwick.

Sir John Batty Tuke has obtained the eighteenth place in the ballot for new Bills which has recently been held. He has therefore put down the Revaccination Bill to which we referred in THE LANCET of Feb. 6th.

Dr. Henry Corby, professor of midwifery, Queen's College, Cork, has been appointed High Sheriff of the city of Cork by his Excellency the Lord Lieutenant of Ireland.

ELEVENTH ANNUAL REPORT (FOR 1902) OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON.

II.[1]

IN that section of his report which treats of the causes of mortality Mr. Shirley Murphy gives an interesting table which contrasts London mortality in 1902 with the average in the preceding decade under certain of the more important headings in the official list of causes of death. The table indicates that disregarding the mortality due to homicide and suicide there are only three diseases—namely, small-pox, cancer, and premature birth—that in the year 1902 were more fatal than usual. Taking all causes together there was a diminution of no less than 6733 deaths in the administrative county of London in the year mentioned, as compared with the average numbers in the previous ten years.

Before proceeding to deal with the incidence of the principal epidemic diseases Mr. Shirley Murphy gives a table which shows the mortality in each of the metropolitan boroughs from the more prevalent diseases which, though not classed as epidemic, nevertheless destroy a large number of lives every year. The numbers upon which the rates in this table are based have been fully corrected for mortality in public institutions, such as workhouses hospitals, and lunatic asylums, whilst in the case of phthisis and of cancer they have been further corrected for age and sex differences of population. The rates given may therefore be regarded as thoroughly trustworthy and may be safely used for comparing the mortality of the several boroughs from each of the included diseases or groups of disease.

In the administrative county as a whole cancer, including therein carcinoma, sarcoma, and other forms of malignant disease, was fatal in 1902 to 93 in each 100,000 of the population. The City of London showed the highest rate—viz., 128 per 100,000—next came Shoreditch with 115, and after these there were 14 other metropolitan boroughs in which the rate exceeded the average. The boroughs of Kensington and Stoke-Newington experienced the lowest rate—viz., 76 per 100,000—and Stepney the next lowest—viz., 79. Phthisis shows a decided tendency to invade with the greatest severity those districts which are sanitarily the most unfortunate, and in this regard its death-rate roughly follows the lead of the death-rate from all causes. Thus, the table indicates that in 1902 the mortality from phthisis, which was equal to a mean rate of 160 per 100,000 in the metropolis generally, was highest (265) in Holborn and next highest (262) in Southwark. On reference to the last column in the table it will be seen that both these boroughs were amongst the areas with very high general rates of mortality. In addition to the above there were nine other boroughs wherein the phthisis-rate exceeded the county average. On the other hand, the metropolitan borough of Hampstead, after making allowance for the deaths in its consumption hospital, experienced the *lowest* mortality from phthisis, which did not exceed 84 per 100,000 living, or less than one-third of the Holborn rate. It is interesting to notice that Hampstead experienced likewise a lower rate of mortality from all causes than any other borough in the county. Pneumonia is also shown by this table to vary greatly in fatality and to invade most severely the least healthy districts. Thus the borough of Hampstead suffered the lowest mortality from this disease—viz., a rate of 75 per 100,000—whilst at the other end of the list came Southwark and Bermondsey, in both of which boroughs the rate was more than thrice as high as it was in Hampstead. The column headed "Other Respiratory Diseases" is necessarily an indefinite one, including, as it almost certainly must, so many conditions of a tuberculous character. The highest mortality from diseases in this group—viz., 315 per 100,000—was returned from Finsbury and the lowest—106—from Hampstead.

---

[1] No. I. was published in THE LANCET of Feb. 6th, 1904, p. 385.

Taking together the principal epidemic diseases—namely, small-pox, measles, scarlet fever, diphtheria, whooping-cough, enteric fever, and diarrhœa—we find that in 1902 they were less fatal than the decennial average by 0·44 per 1000 of the population. The death-rate in London, which was 2·23 per 1000, was higher than that of any other great English town except Liverpool, Birmingham, Bristol, Hull, Salford, and West Ham. As compared with the mortality in the principal foreign and continental cities the mortality from the first six of the epidemic diseases above mentioned was higher in London than in any other city in the list except St. Petersburg.

The event of chief sanitary importance during the year in London was the culmination and decline of the small-pox epidemic, which had increased in the later months of 1901 and continued to increase during the first three months of 1902, *attaining a maximum in March, after which there* was a decline until the beginning of September, subsequently to which the number of cases notified in any week did not exceed eight. The notification of small pox was first made compulsory in the metropolis in the year 1890, but at no period since that date has the incidence of the disease approached that of the year now under notice.

Conformably with previous experience the London epidemic of 1900-02 originated in an imported case. Mr. Shirley Murphy tells us that in the course of this period small-pox was frequently
from Paris, in v
the following
1901, two women in St. Pancras were attacked; their illness had been preceded a fortnight earlier by that of a sister who was a sorter of dirty linen from West End hotels and lodging-houses. This girl's illness had been regarded as chicken-pox. Upon this followed another case in the same house and four cases in the house next door. The illness of these four persons followed that of a girl who died and whose illness had also been regarded as chicken-pox. The laundry girl's attack was apparently the first of the series. From this centre the disease spread throughout the immediate neighbourhood. The next area of attack was in Holborn, where the disease became prevalent in the month of October, especially among the dwellers in common lodging-houses.

About this time a woman who frequented places of this sort in Holborn and Westminster was removed to the Endell-street Infirmary suffering from small-pox. She, however, escaped from the wards and wandered about the district for four days visiting nearly every public house within her reach. We are not surprised to learn that from every public-house into which she is known to have entered one or more patients were removed suffering from small-pox. The disease continued to spread among this class of the population, the common lodging-houses of Holborn, St. Pancras, Westminster, Stepney, and Southwark being especially affected in the last quarter of the year 1901. By this time, Mr. Shirley Murphy tells us, cases of small pox had occurred in every district of London and in St. Pancras (where the disease first assumed serious proportions), in Westminster, and in Holborn the number of cases had either reached or nearly approached the maximum attained during the epidemic. The incidence of the disease in each of the metropolitan boroughs during the whole period covered by the epidemic is well shown by a diagram on p. 29, which is based on the number of small-pox attacks notified in each consecutive week, and in the letterpress Mr. Shirley Murphy has given a detailed and highly instructive account of the spread of the disease from first to last.

It is satisfactory to note that practically all the cases of small-pox that were notified to the sanitary authorities were promptly removed to hospital by the officers of the Metropolitan Asylums Board. In a few instances the nature of the malady was not recognised until the sufferer was found to be dying from a malignant form of the disease and in certain other cases the nature of the disease was only affirmed after recovery. Mr. Shirley Murphy speaks in appreciative terms of the services rendered by the Metropolitan Asylums Board in dealing with epidemic small-pox in London "In no case," he says, "was failure reported to remove to hospital patients suffering from the disease for whose removal application was made." As regards administrative measures for limiting the spread of small-pox we learn that quite early in the epidemic cases of small-pox were mistaken for chicken-pox, because when the graver disease first appeared in London many practitioners of medicine were unfamiliar with its appearance. Consequently the notification of chicken-pox became compulsory in St. Pancras and certain other districts in the autumn of 1901 and in the beginning of 1902 the County Council, with the consent of the Local Government Board, made an order extending this provision to the whole of London. It is a significant fact that within less than three months of the Council's order coming into effect the epidemic began to decline. Nevertheless, the notification of chicken-pox continued to be compulsory in London until January, 1903, by which time the epidemic may be said to have subsided completely. Moreover, the Council in the early part of 1902 appointed
;e of small-pox to
desired a further
In the year 1902
iled themselves of
sing from the con-
y by small-pox, Mr.
Shirley Murphy proceeds to compare the death rate from that disease in London with the rates in the chief towns of England and of the continent. From tables which he has prepared we find that in the period 1892–1901 the London death-rate was exceeded by the death-rates of Liverpool, Birmingham, Bristol, Bradford, Hull, and West Ham, while in 1902 it was considerably higher than the rates of any of these towns except the town last mentioned. As regards the continental towns we learn that whereas the London death-rate in the decennial period just mentioned exceeded that of all the large continental towns except Paris, Brussels, St. Petersburg, Vienna, and New York, in 1902 the London rate was considerably in excess of that of any of these towns.

(To be continued.)

THE CENTRAL MIDWIVES BOARD AND THE TRAINING OF MIDWIVES.

THE following correspondence between the Master of the Rotunda Hospital, Dublin, and the Secretary of the Central Midwives Board has been sent to us for publication.

[Copy.]

of three lying in women daily, with
the puerperium; they take records of
the supervision of the master of the
rs; they receive constant instruction
systematically trained in asepsis and

would be calculated to excite riotous disapproval in the bosoms of long-suffering citizens. It is not, however, very likely that any buildings erected would be reserved in the manner mentioned. The need for workhouses grows with the supply of them and the accommodation for the poor is always insufficient to satisfy the demands of that class of the community. There would be a constant tendency to yield to popular clamour by utilising the facilities available for meeting the distress which is always with us and the net result would be an increase of pauperism quite independent of any war. In a matter of this kind it would be foolish to meet trouble half-way, and however valuable precautionary measures of the nature here referred to might be they would be quite disproportionate to the cost incurred in carrying them out.

THE NEW ARMY COUNCIL.

The following are the names of the members of the new Army Council which is constituted on the model of the Admiralty Board: Mr. Arnold-Forster, M.P., Lieutenant-General Sir N. G. Lyttelton, Major-General Douglas, Major General Plumer, and Major-General Sir J. W. Murray, the Earl of Donoughmore, and Mr. Bromley-Davenport, M.P. Colonel Sir Edward Ward is the secretary. It will be seen that new, as well as relatively young, men have been appointed to carry out the great work of reorganisation before them. We do not notice that one of the ablest and most energetic officers, General Sir William Nicholson, the present Director-General of Mobilisation and Intelligence, has been made a member, nor has the head of the Army Medical Service any place in the council. No one has yet been nominated to the post of Inspector-General of the Forces. It has been suggested that Lord Roberts should fill the post but it is not at all certain that the present Commander-in Chief would be willing to do so even were it not opposed to the view which has been made a great point of—viz, that new measures require new men.

THE DIRECTOR-GENERAL AND THE WORK OF THE OFFICERS OF THE ROYAL ARMY MEDICAL CORPS.

In his address to the Lieutenants on probation at the opening of the eighty-eighth session of the Royal Army Medical College Sir William Taylor, K.C.B., remarked: "It is said that the practical experience of the army doctor is confined to treating the diseases of early manhood and that this limitation of practice leads to stagnation of effort and to blunting of mental acuteness and judgment. Believe me, there is nothing further from the truth. No army medical officer need let his knowledge rust; his opportunities for keeping himself abreast of the knowledge of the times are as good and, I think, even better, than those of the doctor in civil practice. There is abundance and variety of clinical work to be found in our army hospitals. The field of the army surgeon is world-wide and in the domain of tropical medicine he will find a field for observation and research that affords opportunities for practice and progress that no other section of our profession possesses."

"Audi alteram partem."

THE CAUSES OF HIGH INFANTILE MORTALITY.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Jan. 30th, p. 334, there is a letter from Mr. J. Theodore Dodd in which he suggests that in those town unions which give very little out-relief the infantile mortality is higher than in those which give a fair amount of out-relief. As one who has given very great attention to this question I can assure him that a high or low rate of out-relief has no more to do with a high or low rate of infantile mortality than Tenterden steeple has to do with Goodwin Sands. He quotes Liverpool and Manchester and compares them with four other large towns; they are not comparable as regards the administration of the Poor-law for this reason: Liverpool and Manchester Poor-law areas number 2470 and 1646 acres; the cities 8133 and 7960 acres. The former are densely populated districts with any number of hospitals and dispensaries, but that does not suffice to keep down infantile mortality, though the last report of the medical officer of health of Manchester shows an improvement as the mortality in 1902 was only 151. If Mr. Dodd will look down his list he will see that his first dozen unions in London are all densely populated, the last half-dozen London unions much less so, and this is also the case with Sheffield (10,000 acres) and Leeds (13,000 acres). Now as Mr. Dodd has referred to Manchester it may be useful to see what the figures are for the three divisions into which Manchester is divided (Table I.).

TABLE I.

—	Persons to an acre.	Proportion of deaths under one year.
Manchester township ...	81	168
North Manchester	23	139
South Manchester	63	150

If Mr. Dodd will turn to the Registrar-General's return he will find that the lowest infantile mortality is found in Rutland, Dorset, Wilts, and Oxford (79 to 100), all agricultural counties. At the other end of the scale we have Warwick, Nottingham, Stafford, Yorks (East Riding), and Lancashire.

TABLE II.

—	*Infantile mortality per 1000.*	*Illiterate women per 1000 marriages.*	Percentage of out relief
Rutland	79	23	62.6
Dorset	91	14	73.1
Wilts	94	12	65.0
Oxford	100	14	65.5
Hereford	106	34	67.2
Hertford	110	22	65.9
Westmorland	110	22	51.8
Bucks	112	11	74.1
Somerset	112	23	70.4
Shropshire	113	28	42.6
Berks	115	17	41.3
Sussex	117	10	54.0
Bedford...	117	24	73.0
Cambridge	118	28	67.9
Surrey	120	10	41.0
Gloucester	120	29	62.1
Northampton	122	23	73.3
Suffolk	122	20	63.2
Cornwall	126	42	77.3
Hampshire	127	11	56.5
Huntingdon	127	6	57.2
Kent	130	17	45.1
Devon	133	15	73.8
Lincoln...	138	21	79.6
North Wales	138	52	62.2
Worcester	141	37	51.5
Middlesex	142	12	43.9
Norfolk...	142	24	67.7
Cumberland	144	29	62.5
Cheshire	147	30	56.0
Monmouth	150	64	70.1
Derby	152	21	70.0
Yorks (North Riding)	154	36	64.3
South Wales	154	50	76.0
Essex	155	23	50.8
Leicester	156	18	66.1
London	160	32	20.1
Northumberland ..	165	34	56.3
Yorks (West Riding)	166	39	54.5
Durham	167	40	58.6
Warwick	175	36	40.3
Nottingham	176	33	66.7
Stafford	178	44	57.3
Yorks (East Riding)...	179	24	64.2
Lancashire	180	41	37.2

all manufacturing counties with large numbers of women employed in the cotton, metal, and woollen works This fact plays an important part in causing the large infantile mortality, because even if the mother does try to nurse her child while going to work at the factory the intervals between the time of feeding the infant are too long, but in a very large number of cases the baby is put out to nurse with all the horrors associated with this practice I think that if Mr Dodd will look down Table II he will see that it is not strict out-relief that is the cause but something which affects larger masses of the people than those who receive relief from the rates

I am, Sirs, yours faithfully,
Didsbury, Feb 8th JNO MILSON RHODES, M D Brux.

MALIGNANT GROWTHS AND NORMAL REPRODUCTIVE TISSUES

To the Editors of THE LANCET.

SIRS,—I read with great interest the leading article in THE LANCET of Jan 30th, p 311, which directed attention to the communication of Professor J B Farmer, Mr J E S Moore, and Mr C E Walker to the Royal Society, the abstract of which in THE LANCET of Dec. 26th, 1903, I had unfortunately not seen I am especially pleased that work is being done in this direction, as, although I have never prosecuted any research myself, I have thought for some years that the line of inquiry now being undertaken by Professor Farmer and his colleagues, and also by Dr E F Bashford and Dr J A Murray, would be likely to yield good fruit

In 1898 when president of the East Yorks and North Lincoln branch of the British Medical Association, I chose the subject of malignancy for my introductory address In this paper, which was published in the *Quarterly Medical Journal* for July, 1898, I reviewed all the hypotheses which had been advanced in order to explain the causation of cancer I er
bet
con
way into the underlying mesoblast, the cells undergoing rapid division with an abundant blood supply) and the growth of a malignant tumour And the analogy is made closer by the fact that glycogen, which is present in large quantities in the fœtal cells had also been found by Langhans of Berne and by Creighton in this country to be a constituent of cancer cells I referred to Hansemann's work on karyokinesis in malignancy In his monograph he says that in normal tissues, although the number of chromosomes may vary largely in different kinds of cells, the numbers are always even numbers, but that in malignant growths the shape of the karyokinetic figures may differ largely from the normal and that the number of chromosomes may be odd How these asymmetrical forms are produced he did not know but he maintained that they were peculiar to cancer I then continued "So far as our present knowledge extends there are points of resemblance, both morphological and physiological, in the growth of a malignant tumour and the development of an organ in the fœtus The presence of asymmetrical mitoses in cancer, whether peculiar to it or not, is certainly remarkable and it yet remains to be seen how these forms are produced It seems to me most likely that we shall find their prototype in the normal structures As I have said all normal cells when dividing possess an even number of chromosomes and when the chromatin filaments split there must always be an even number in the two daughter cells Is any other mode of division of the filaments known? Is there any physiological exception to the ordinary method by cleavage of the chromatin threads? There is one such exception and I cannot help being struck with the fact and with its possible bearing on what I have said regarding the analogy between the growth of a tumour and that of the fœtus The exception is in the mode of formation of the generative cells, the spermatozoa and the ova In the division of the spermatogenic cells of the testicle to form the spermatoblasts or young spermatozoa the final separation of the chromosomes into the daughter nuclei takes place without the occurrence of a corresponding longitudinal cleavage, the result of this is that the spermatoblasts contain only half the usual number of chromosomes, consequently the male pro nucleus also is formed by half the usual number The same may be said of the female pro nucleus which has parted with one half of its chromosomes in extruding the second directive corpuscle This work on the generative cells has hitherto been confined to the lower forms of life and no observations have been made, as far as I can learn, on mammals—that is, regarding the number of chromosomes—but it is obvious that should the spermatogenic cells contain 2, 6 10, 14, &c, chromosomes, the spermatoblast will contain 1, 3 5 or 7, or odd numbers of chromosomes Most of the cells worked at contain 8, 12 16, or 24, so that there would be 4 6, 8 or 12, or even numbers in the spermatoblast But Carnoy has described a nematode with six chromosomes in the generative cells which would give an odd number after division It is hence quite possible that the generative cells of mammals may contain an odd number of chromatin filaments and as these cells under certain circumstances possess the greatest possible power of division and reproduction it may be that the analogy between tumour growth and its physiological prototype may be pushed still further The idea is, of course, quite speculative and of no real value unless supported by observations on the number of chromosomes in mammalia, which have not yet been made so far as I am aware, still, there is no evidence against it and I think it may be put forward as a provisional hypothesis which will stand or fall according to observations recorded in the future" In conclusion I said "For my own part I am inclined to the belief that the cause of malignancy will only be explained when we know more concerning the cause of the development of fœtal organs"

I am Sirs, yours faithfully,
EDWARD HARRISON, M D Cantab, F R C S Eng
Hull, Feb 3rd 1904

To the Editors of THE LANCET

SIRS—I hope you will pardon me if I return to the interesting and stimulating discoveries of Professor J B Farmer, Mr J E S Moore, and Mr C E Walker, and Dr E F Bashford and Dr J A Murray The former have demonstrated that nuclear changes occur in cancerous tissues by which cells of malignant growths may be justly considered homologous to active sexual elements ("gametoid") Giant cells are suggested to be "fusion figures" which recall normal fertilisation (*sic*) in cancer I write to ask if botanists or zoologists are of the opinion that post heterotypic cells (homotypic) are at all 'inclined' to develop without fertilisation—i e, by parthenogenesis from (?) chemical stimulus Does parthenogenesis occur in the embryo sac of flowering plants or in the prothallium of the higher cryptogams under any and what state? On what known conditions does parthenogenesis in the eggs of the honey bee, in ascaris, in artemisia, &c, depend? This sexual character of the cells of cancer explains partly its parasitic and invading nature; the wonderful power of mimicry of the tissues from which they originate however might suggest easily that the metastases commence as cells self fertilised and maturating A knowledge of the (? chemical) causes underlying both these changes might afford a clue to prevention

I am, Sirs, yours faithfully,
Plymouth Feb 9th 1904 F BUSHNELL, M D Lond

PS—I should add that Dr Bashford and Dr Murray in no way interpret the significance of the mitoses in cancers as evidence of new growths being reproductive tissues

---

THE PROPOSAL TO PROHIBIT MEDICAL PRACTITIONERS FROM DISPENSING

To the Editors of THE LANCET

SIRS—As it would appear from the letters of "Paganus," "Surgery" and "M R C S, L S A," in THE LANCET of Feb 6th that serious misapprehension exists as to the origin and present position of certain proposals to add new clauses, affecting dispensing by medical men, to the draft Medical Acts Amendment Bill which is now under consideration by the divisions of the British Medical Association I trust that you will be kind enough to insert in your next issue the following explanation which I am authorised to give

The Medical Acts Amendment Bill, prepared by the Medico Political Committee of the Association, was remitted in August last to the divisions of the Association for preliminary consideration and the full text was published in the supplement to the *British Medical Journal* of August 18th last. It contains no reference to the subject dealt with by your correspondents. As a result of the preliminary consideration by divisions the Bill will shortly be re-drafted and will again be submitted to the divisions in order that its provisions may be voted on by the annual representative meeting of the Association, commencing at Oxford on July 26th.

In the process of consideration of the matter by the Central London division (not the Metropolitan Counties Branch as apparently supposed by your correspondent, Dr. J. Oliver, and stated in your leading article on Jan. 23rd), an individual member of that division has given notice that he will move in favour of adding to the Bill clauses to prohibit dispensing by medical men except in certain circumstances specifically stated. His motion will be considered by the division on Feb. 17th.

It will thus be seen that not only do the clauses in question not form part of the Medical Acts Amendment Bill as originally drafted by the Medico-Political Committee and not only have they not received any kind of sanction from the Association; they have not even been so much as considered up to the present by any division of the Association. I am, Sirs, yours faithfully,

J. SMITH WHITAKER,
Feb. 8th, 1904. Medical Secretary.

To the Editors of THE LANCET.

SIRS,—I have read with much interest your leading article and Dr. J. Oliver's letter on a proposal in the Draft Bill of the British Medical Association to prohibit medical men from dispensing medicines, and I quite endorse the views so well expressed in THE LANCET of the 23rd ult. While a progressive in every sense of the word in medicine as well as in politics I yet believe that we owe much regard and reverence to the past. This subject of dispensing our own drugs has awakened in my breast many old memories, and without discussing the question further on the lines of Dr. Oliver, whose reasoning is sound and irrefragable, I should like, with your leave, to say a few words in this connexion from a retrospective and sentimental point of view.

Some 45 years ago I made the acquaintance in a quiet Scottish village of a man of the highest culture and most courteous manners, with a somewhat wide experience, I have ever known. To myself, a raw beginner, he was most kind. Although my setting up in practice in his neighbourhood might possibly have affected his pocket, he nevertheless was uniformly ready to lend me wise and disinterested advice and assistance. He was indeed in my youth my "guide, philosopher, and friend," and looking back over my past life he was as much my teacher, in the best sense of the word, as were the host of mathematics and anatomy, the other two great factors which have profoundly affected my whole career, such as it has been. 40 years ago, when I was in the habit of visiting my friend, if I did not find him in the shop (he was not ashamed of the title) we were sure to gravitate to that centre. At that period he did not have there his well-plenished wine-cellar, though later on, with its gradual disuse as a drug store, it came to be used for that convivial purpose. How many good stories did its walls call up in the days when his worthy father, a distinguished surgeon of his day (now nearly a century ago) kept a small army of apprentices. But I wish at this time to recall the shop, not for its esoteric relations but for its exoteric influences. There had his father laboured and there had my friend grown up from boyhood to manhood among his fellow citizens. The shop door was always open and the practitioner's advice, mostly without fee or reward, always ready for the benefit of his neighbours, for the poor as well as for the rich—advice not only professional but as often as not on matters of business and conduct. And so the motto "*Nihil humanum a me alienum puto*" should before all be our motto, a motto as old as the days of Hippocrates. And if so, is there not a considerable risk of our losing hold of the regard and, it may be, the affections of our patients by standing aloof too much from their daily lives and neglecting the exercise of our immediate sympathies for their behoof? As has been so well said by John Brown (it does one good to write that fine, wholesome, common name): "It is not a case we are treating; it is a living, palpitating, alas, too often suffering fellow creature."

And is there not the danger of becoming ultra-scientific over much of our wise friend Gardener's "naturalist" in medicine and too little of the good old-fashioned Samaritan with his supplies of oil and wine ready in his wallet to administer to the weary wayfarer in life's thorny path of sickness and disease. Charity at second hand is a poor substitute for real brotherly kindness. "Mittened cats do not catch mice." In other words, the true healer must not only be skilled in what to do but be thoroughly acquainted with how to do it. And this implies a readiness of hand and a constant seeing and handling of the weapons or the adjuvants with which he is to fight the elements of disorder, derangement, and it may be death. In this age of specialism, with all its blatant victories—victories which I do not for one moment despise—no thinking person can deny that the every-day skill and attention of the humblest practitioner, our Gideon Grays and MacLures, may, like the quality of mercy and the gentle rain distilled from heaven, do a thousand times more for sweetening the lives of humanity at large than all the triumphs of the greatest and mightiest and most successful of our surgeons and physicians.

I am, Sirs, yours faithfully,
Feb. 2nd, 1904. W. B.

To the Editors of THE LANCET.

SIRS,—I bought a practice in a poor neighbourhood the *private* receipts from which are about £150 per annum; in addition to this I have in *contract* or friendly society work four clubs; they are my mainstay, they pay £300 per annum and give little trouble; some members pay 4s. and others 5s. per annum. This makes my practice worth £450 per annum. It took me four years to work this up; competition is keen. Now if I were not allowed to dispense I should be *hopelessly ruined*, for very few of my private patients could afford to pay medical man and druggist; and as regards the contract work I discussed the above question with the secretaries of the clubs and offered attendance at a reduced rate conditionally that they would obtain medicines from and pay the druggist. The answer I got was that they preferred to get medicines and attendance from me as hitherto and, failing this—and here's the rub!—they would unite with three large clubs belonging to my neighbours and form a "friendly societies' medical institute," put all their families in, and get a surgeon to give his whole time to the work. This means that the population of the place would be well depleted by the institute and four of us would be swamped. This is only one instance in which a general practitioner like myself—*plus* three brother practitioners—would be hardly hit or else ruined. I hope and pray that the advocates of this cruel and absurd idea will be frustrated in their attempt to legalise a scheme which would mean the *absolute ruin* of hundreds of hard-working, conscientious men who attend the poorer section of the community—I mean those able and willing to pay a *small* fee and who would otherwise go to the hospital or provident dispensary. To the rank and file of the general practitioners I say, "Wake up!" and strenuously oppose the Bill for the "prohibition of dispensing by doctors."

I am, Sirs, yours faithfully,
Feb. 6th, 1904. L.R.C.P., &c.

To the Editors of THE LANCET.

SIRS,—Your announcement of a meeting of a branch of the British Medical Association about to be held to consider certain new clauses which it has been suggested shall form part of the Medical Act Amendment Bill, and more particularly the clause respecting the dispensing, has led me to write you to call attention to another matter which I think bears as hardly on the medical profession as it does on the public. I write as a chemist and would be glad to see the proposed new clauses *re* dispensing adopted. It is, however, a matter that must, I think, be left to the medical profession. Our society has done its duty and to-day there are capable qualified men in every legitimate chemist's shop in Great Britain waiting hopefully for the time when medical men shall delegate their "dispensing." This by the way. What I took up my pen to write about is the question of *prescribing*.

I want to point out that the prescribing chemist, speaking broadly, is non-existent; the old school is perhaps represented here and there but for practical purposes there are no prescribing chemists. But to-day illegitimate prescribing is more practised, more far-reaching, more detrimental, alike to the public and to the medical man, than ever it has been at any period The prescribing chemist has given place to the daily newspaper and magazine and the public swallow the quack nostrums there prescribed and so blatantly advertised and pay out their half crowns without hesitation, in the majority of cases losing their money and vitiating their health in a stupendous, wholesale style never previously dreamed of Never have the ailing public been *so exploited Great Britain has become the happy* hunting ground of the American professor of humbug and a rich harvest is being gathered by means of positive statements that applied to any other commercial transaction would assure prompt arrest and punishment Why is it the law permits the statement that "Dr Blank's Blue Pills' will cure locomotor ataxy, paralysis, and the like, and yet when the poor sufferer has spent his money and proved the fraud of the label the law offers no facilities for prompt punishment of the fraudulent vendor?

It is rumoured that owing to a recent legal ruling the *authorities charged with the collection of revenue from* these quack nostrums will shortly introduce an amending Act into Parliament widening the scope of its Acts If this is done the medical profession should see to it that in future the Government should free itself from its association with quackery either by insisting on the actual formula being published on the outside of every package (as on the continent) or in some other distinct manner withdraw the sanction which its medicine stamp now extends In view of the recent disclosures by a medical man (as reported in THE LANCET) of the ingredients of these nostrums the public will not need *anything further to show them the "folly of their* faith' than a knowledge that the actual ingredients of their favourite nostrum can be purchased for a few coppers Apart from any other considerations it is pitiful to see the way the very poor are defrauded of their money and often when they need it most The Government should do something to protect the ignorant or, at all events, in common decency they should dissociate themselves from a "connivance with quackery and the medical profession should not hesitate to speak firmly on the subject

I am Sirs yours faithfully,

Feb 8th 1904 *A CHEMIST AND DRUGGIST*

THE ANGLO AMERICAN MEDICAL ASSOCIATION OF BERLIN

To the Editors of THE LANCET

SIRS —The Anglo American Medical Association of Berlin will be glad if you would inform the profession of its organisation and purposes Realising the difficulties which beset the path of the stranger, the association places its

end to study in
id the meetings
concerning the
any member of

the profession who will communicate upon his arrival in Berlin with Dr J H Honan president Lutzow Str 78, or with the undersigned committee

We are Sirs, yours faithfully,
ALBERT J MAYER M D , Secretary
DAVID SHANNON M B Glasg
WILLIAM W GRAVES M D

Albrecht Str 22 Berlin Feb 3rd 1904

SPORADIC SMALL-POX

To the Editors of THE LANCET

SIRS,—Wherever a sporadic case of small pox occurs and there is no history of infection the question must naturally puzzle one as to the origin of the disease Quite recently a case of small pox occurred in my district and, like many other cases so far as could be ascertained by questioning the patient, there was absolutely no history to answer for the infection The house in which the case happened was dark and exceedingly dirty, and the rooms had a large number of papers upon the walls which were infested with bugs During the outbreak of small pox at the end of the year 1901 and the beginning of the year 1902 the stripping and cleansing of rooms previously to lime whiting revealed large numbers of papers upon the walls of houses which were terribly infested with bugs The amount of pent up filth to my mind was so alarming that in reporting to my public health committee respecting the working of the sections of the Public Health (London) Act 1891, which govern the cleansing and disinfection of houses, *inter alia* I stated —

> Some of the rooms which were stripped after the cases of small pox had 18 15 12 and 10 papers on their walls The amount of pent up filth must be enormous and it is not reasonable to expect tenants to
>
> together the plaster If such a state
> on the houses of the working classes in Lon on w i i i t n e become so saturated with filth and disease that a condition of affairs in the metropolis will be arrived at like that in the year 1665 when plague broke out

Recent researches in respect of mosquitoes being the carriers of malaria and of fleas being the means of conveying plague from infected rats suggest an idea as to whether there is any condition of a bug externally or internally which causes small pox I must apologise for writing on what may be considered so puerile a matter, for the question may be derisively asked what about lice and black beetles, but the walls of the houses which were cleansed, disinfected and lime whited had so much pent up filth upon them by the plastering of paper upon paper that possibly the surroundings of the bugs had affected their condition or excreta and any ideas which may suggest to bacteriologists new fields to work on in order to discover the origin of so loathsome a disease as small pox which must originate from some cause I am sure, cannot be amiss

I am Sirs yours faithfully,
FREDK WM ALEXANDER
Medical Officer of Health Metropolitan Borough of Poplar

Bow road E Feb 2nd 1904

THE TREATMENT OF SCOLIOSIS

To the Editors of THE LANCET

SIRS —In the report you give in THE LANCET of Jan 30th, p 302 of my paper on the above subject read before the Aberdeen University Medical Society there are several passages which give an entirely erroneous impression of what I said

1 ' In *osseous scoliosis there was bone disease* and the condition was to that extent incurable ' What I said was that ' there was bony *deformity* and the condition was to that extent incurable

2 of the

cases

Thi —viz , postural and osseous combined about one half have an *ordinary* (not reversed) letter C curvature of the whole dorsal and lumbar vertebræ (not only the dorsal region) '

3 The muscular sense was markedly *absent* in the *wasted muscles*

Surely the patient s muscular sense is *perverted* not *absent*, for the vicious posture appears to her quite natural while the improved position in which she is put by the surgeon appears to her, through her perverted muscular sense to be totally incorrect If the muscular sense were absent it would be a waste of time to treat the patient at all I should be obliged if you would insert this in your next issue, as such errors are very misleading and tend to discredit the very valuable method of treatment which I was advocating

I am Sirs yours faithfully,
P BERNARD ROTH

Marischal College Aberdeen Feb 2nd 1904

⁂ We have referred the above letter to our correspondent in Aberdeen who replies that his report "gives a very reasonable gist of the lecture' and was not intended to be *verbatim* To the first and third emendations he demurs, the second one he admits to have point and accepts the correction with regrets for the slip In these regrets we join —ED L

CHLORETONE IN SEA-SICKNESS

To the Editors of THE LANCET

SIRS —In a recent issue of THE LANCET experiences were invited with regard to the treatment of sea sickness by chloretone I notice several medical men have given the experiences of their patients but I shall venture to place before you my own personal experience of the action of this drug I am always a bad sailor and when it recently became necessary for me to visit the continent I determined to give chloretone a fair test. Not having taken a voyage for five or six years, I practically left myself untreated on the voyage over which lasted some four hours, to test my seafaring qualities. It was fairly rough but I tried to brave it out, remaining on deck. I was, however, soon completely overcome and before reaching the continental port was very much in the condition of the man who at first was afraid he was going to die, but a little later was afraid he was *not* going to die. On this occasion when nausea came on I took a dose of chloretone which had no beneficial action, but the test not being a fair one I pass it by. On the return voyage, however, I determined to give the drug every chance. Having one and a half hours' railway journey before joining my boat, I took ten grains of chloretone on beginning this portion of the journey, repeating the dose just before going on board. I remained quietly reclining on deck and took a third dose about an hour after sailing, thus having 30 grains in from two to three hours. The result was absolutely unsatisfactory and during the second half of the crossing, which this time likewise was fairly rough, I was as ill as I ever was before. Furthermore, the nausea lasted rather longer than usual after landing, but this I put down to mere coincidence. Chloretone in my case proved absolutely useless. A lady doctor of homœopathic tendencies gave me some high-grade petroleum tablets to try. I undertook to do so only in case the chloretone failed and when it was evident that it had I took the petroleum tablets but without avail. I know chloretone is successful with some individuals, but it failed in my case after a most fair trial.

I am, Sirs, yours faithfully,
South Kensington, Feb. 5th, 1904. L. ERASMUS ELLIS.

To the Editors of THE LANCET.

SIRS,—Under the above Mr. Cameron Kidd, in THE LANCET of Jan. 30th, p. 334, reports an interesting case of "train sickness" in a little girl successfully treated with chloretone. In THE LANCET of June 8th, 1895, p. 1434, I drew attention to such cases, recommending sulphonal in varying doses. Common as it is in children, as I pointed out, and trivial as it may seem amongst adults, "railway megrim varies from undue fatigue and inability to sleep the same night to intense headache, sickness, and prostration," and there are many "in whom a railway journey of two hours produces as much dread and misery as a sea passage." At the time of my communication I recollect receiving more than one grateful letter from readers of THE LANCET and since I have often used myself and recommended sulphonal or trional with success. Still, in some cases I have failed and I am especially obliged to Mr. Kidd for his recommendation of chloretone.—I am, Sirs, yours faithfully,
Feb. 9th, 1904. JOHN A. SHAW-MACKENZIE, M.D. Lond.

THE REVACCINATION BILL, 1904.

To the Editors of THE LANCET.

SIRS,—I do not see in the draft of this Bill printed in THE LANCET of Feb. 6th any procedure described to secure the revaccination of children in lunatic asylums.

I am, Sirs, yours faithfully,
W. H. BOWES.
Plymouth Borough Asylum, Ivybridge, Devon, Feb. 9th, 1904.

THE INQUEST ON WHITAKER WRIGHT.

To the Editors of THE LANCET.

SIRS,—Mr. D. Biddle in his well-argued letter in THE LANCET of Feb. 6th, p. 394, on the inquest of Whitaker Wright says, "The bluish tint of the body and the fluidity of the blood are neither separately nor together distinctive of poisoning by prussic acid." As to the fluidity of the blood I cannot speak positively, but I think that if the body is seen soon after death the blue colour may be looked upon as pathognomonic of poisoning by hydrocyanic acid.

Some years ago I was first impressed with this fact by a melancholy case of poisoning by prussic acid which came under my observation. The subject was a handsome, fair-skinned, young man who, in a fit of temporary insanity, drank an ounce of hydrocyanic acid. I saw him a few minutes after he had swallowed the fatal draught lying dead on his bed and the empty bottle, which had evidently contained the acid, was on a chair by the bedside. As regards the appearance of the body, the first thing that attracted my attention was the brilliant violet colour which the skin presented. Several hours afterwards when I again saw the body the violet colour had considerably faded. The intensity of the colour in this case may have been owing to the large quantity of poison taken. Dr. Taylor, in his book on Poisons, mentions a violet colour as one of the appearances met with after death from poisoning by hydrocyanic acid.

I am, Sirs, yours faithfully,
WILLIAM O'NEILL, M.D. Aberd., M.R.C.P. Lond., &c.
Lincoln, Feb. 6th, 1904.

THE DESTRUCTION OF TUBERCULOUS SPUTA.

To the Editors of THE LANCET.

SIRS,—I notice in a paper by Dr. C. T. Williams that he advises as a convenient method of destroying the expectoration of tuberculous patients mixing it with sawdust and burning it. For some years I have advocated the following plan which appears to me a more complete system. A small *cardboard box is half filled with sawdust which is damped* with paraffin. Into this the patient expectorates and at the end of the day it is easily burnt. Even in the summer when there may be no fire, a match will be sufficient to cause its total destruction. Most householders have a superfluity of such boxes and are pleased to find a use for them. If a cup is used or a bottle to carry about it is quite easy to have a lining of greased paper which can be lifted out with its contents each night and burnt.

I am, Sirs, yours faithfully,
J. LIONEL STRETTON,
Senior Surgeon, Kidderminster Infirmary and Children's Hospital.
Feb. 2nd, 1904.

MEDICAL ACTS AMENDMENT BILL.

To the Editors of THE LANCET.

SIRS,—I am glad to learn from THE LANCET of Jan. 30th, p. 339, that Clause 34 of the Medical Acts Amendment Bill has met with adverse criticism at the meeting of the Cardiff division of the British Medical Association. My surprise is that any division has tolerated it. In my opinion it is quite unnecessary to protect the profession from unqualified practitioners and would certainly be very detrimental to the interests of the general practitioner. Few of us in such conditions would care to employ an assistant and an additional hardship would be thrown on those who are obliged to. In addition to the increased facilities given to an unscrupulous assistant to pretend to partnership there is the obvious harm likely to arise to a practice from the open advertisement in connexion with it of men who, later on, may become notorious black sheep. Considering the complaints so often made in the medical press of the class of practitioner too frequently foisted on us as assistants, and that two months is far too short a time for the principal to find out the character of his assistant, the exemption suggested is practically of little use.

For my own part, if this clause is retained I would rather see the whole Bill—which in many points is an excellent one—lost, so detrimental do I consider the conditions it lays down to the best interests of the general practitioner.

I am, Sirs, yours faithfully,
MAJOR GREENWOOD, M.D. Brux., LL.B.,
Barrister-at-law.
Hackney-road, N.E., Feb. 4th, 1904.

THE TEACHING OF BIOLOGY.

To the Editors of THE LANCET.

SIRS,—In July last a committee appointed by the Royal Colleges of Physicians of London and of Surgeons of England to consider what alterations, if any, were desirable in regard to the conduct of the First Examination of the Conjoint Board issued a report containing certain suggestions which deal, *inter alia*, with the teaching of biology. The report has been adopted by the Colleges and in pursuance of its recommendations an attempt is now being made by the committee to elicit the opinions of teachers in the metropolitan and provincial schools on the following points:—

1. What alterations, if any, are desirable in the synopsis for elementary biology?

2. Is it desirable that there should be a paper in biology in addition to the *vivâ-voce* examination?

3. If so, how many questions should be set in the paper and how many hours allotted to it?

4. Should the candidates be required to answer all the questions or should they be allowed a choice?

Of these questions Nos. 2, 3, and 4 deal with matters of detail which may well be left to the decision of the representatives of the various schools, but the first raises larger issues and makes the present an opportune moment for the consideration of the place of biological training in medical education. In all seriousness it may be asked whether a course of lectures and demonstrations on anything like the present lines has a value in the least commensurate with the time it must occupy even if, as suggested by the committee, some portion of the course is gone through elsewhere than at a medical school and before the preliminary examination in general education is passed.
